Trade.—In 2000, 46% of world iron ore production was exported, down from 47% in 1999. At 1,061 Mt, world exports increased by 11%. Australia was the leading exporter of iron ore, shipping 165 Mt to world markets, followed by Brazil, which exported 160 Mt, and India, which exported 35 Mt. Australia and Brazil continued to increase their domination of the global export market, with 67% of the total in 2000. In decreasing order of market share, Australia held 34%, Brazil 33%, India 7%, and Canada 5%. No other exporting country had as much as 5%. Western Europe and Asia accounted for 83% of world iron ore imports in 2000. Japan, as usual, was the leading importing country, accounting for 27% of imports. The next largest country was China, which imported 14%, followed by Germany at 10% and the Republic of Korea at 8%. Japan, China, and the Republic of Korea accounted for 50% of world iron ore imports in 2000.

Mergers and Acquisitions.—There was major merger activity in 2000 and it all, directly or indirectly, involved the two primary iron ore exporting countries, Australia and Brazil. Behind the trend was a need for iron ore producers to become larger to achieve economies of scale and to put themselves in a better bargaining position with individual customers who were themselves becoming larger through consolidation.

In August, Rio Tinto Ltd. completed a hostile takeover bid for North Ltd. of Australia and Canada (Kirk, 2000b). CVRD of Brazil was then and still is the world's largest iron ore producer. The next largest, situated in Western Australia, were the Broken Hill Pty. Co. Ltd. (BHP), Hamersley Iron Ore Pty. Ltd., a wholly owned subsidiary of Rio Tinto, and in Western Australia and Canada, North Ltd. As a result of the takeover, Rio Tinto, sole owner of Hamersley, became the second largest iron ore producer in the world followed by BHP. The North takeover bid came about a year after the collapse of Rio Tinto's negotiations with BHP over the pooling of the two companies' iron ore operations.

Anglo American plc, of London and Johannesburg, South Africa, made a counter bid. Anglo's offer was backed by the Japanese steel mills who were concerned that the consolidation of Western Australia's iron ore mining industry would weaken their bargaining position during price negotiations. The Japanese steel companies have long-term supply contracts with the three Australian mining companies, but renegotiate prices annually. In early August, Rio Tinto countered Anglo's bid and shortly thereafter North's directors recommended that shareholders accept Rio Tinto's increased bid.

Rio Tinto acquired a majority position in three large iron ore assets. Two of them are mining operations, Robe River Iron Associates in Western Australia and the Iron Ore Co. of Canada (IOC) in Canada. The third asset, the West Angelas deposit in Western Australia, was the primary target of Rio Tinto's interest in North Ltd. The West Angelas deposit is 300 km southeast of Robe River's port at Cape Lambert. In March 2000, the West Angelas Development was formally endorsed by the Western Australia Minister for Resources Development, enabling work to begin on the project The project has received all other Western Australian and Federal Government approvals. North had planned for production to begin in 2002 at a rate of 7 Mt/yr, rising to 20 Mt/yr in several years. Resources were reported to be at least1 billion tons, with 440 Mt of proven and probable reserves in two adjacent deposits. North expected that lump ore would comprise 33% of production. The development of West Angelas was underpinned by letters of intent from the Japanese steel industry to buy its production, one of the primary factors in Rio Tinto's decision to buy North. The tonnage to be purchased was to be 5 million dry long tons in 2002-03, increasing to 8 million dry long tons in the fourth year and thereafter. Construction contracts began to be let late in 1999, so that Robe River could meet customer demand for delivery in mid-2002.

Mergers in the mining industry generally do not have as much potential for synergy as they do in other industries because mining companies usually cannot share infrastructure. Mines cannot be moved, and most savings would come from consolidation of staffs. The Rio Tinto-North merger is a notable exception because the two companies can easily share infrastructure. The West Angelas deposit is about 50 km from Hamersley's rail line to Yandi. Thus, Rio Tinto could gain access to West Angelas by constructing a short spur rather than a 340-km rail line.

This acquisition resulted in a number of benefits to Rio Tinto. One of the more important benefits was that, as a result of acquiring very large iron ore deposit located close to its rail line, Rio Tinto should be able to make a major increase in its production rate with low production costs. It also boosted Rio Tinto's reserves. Another benefit was the addition of a port in Western Australia. The rail line from North's existing mine in Western Australia crosses the Hamersley rail line, and Rio Tinto could divert iron ore from Mesa J to Rio Tinto's own port at Dampier, providing greater flexibility. Hamersley also would probably be able to cancel, or postpone, the development of its Nammuldi Marra Mamba deposit because the West Angelas also has Marra Mamba type ore. Another benefit is that Rio Tinto's headquarters and North's main office are both in Melbourne, which would simplify the merger of corporate activities. One of the most important benefits is the increase in size. With the addition of IOC and Pannawonica, Robe River's iron ore mine in Western Australia, Rio Tinto has put itself in a better bargaining position. The beginning of production at West Angelas will enhance that position.

A possible disadvantage is the desire of the Japanese steel mills for a rail line between West Angelas and the Hamersley-Robe River rail crossing about 70 kilometers from Cape Lambert. The Japanese steel mills say that there is a strong

Digitized by Google

likelihood that production at the West Angelas Mine could increase to 40 Mt/yr to 50 Mt/yr, and a new rail line would be required to handle it. Under the terms of the Robe River joint-venture agreement, which governs the West Angelas project, Rio Tinto will be unable to reverse the unanimous decision to develop the West Angelas project, inclusive of the new railway construction, as per the resolution dated March 6, 2000. Seen as a whole, the benefits to Rio Tinto far outweigh the disadvantages. If Rio Tinto follows North's expansion plans of producing 20 Mt/yr from West Angelas and 45 Mt/yr from Pannawonica by 2010, Rio Tinto could be producing 104 Mt/yr by the end of the decade (Metal Bulletin, 2000u). The near-term effect was that Rio Tinto's iron ore production rose 40%, increasing from 51.8 Mt in 1999 to 72.5 Mt in 2000 (Metal Bulletin, 2001).

Late in the year, Rio Tinto announced that it intended to raise its stake in IOC from 56.1% to 75% by making a $266 million ($8.90 per unit) offer to Labrador Iron Ore Royalty Income Fund. The fund owns an 18.9% stake in IOC through its wholly owned subsidiary Labrador Mining and Exploration Co. Ltd. The remaining 25% in IOC is held by Mitsubishi. The offer, which is being made through Rio Tinto's wholly owned subsidiary, Rio Tinto Canada Inc., was to be conditional on the acceptance of 75% of the unit-holders and regulatory approval (Rio Tinto, December 15, 2000, Offer for Labrador iron ore Royalty Fund, Media Release, accessed on February 15, 2001, at URL www.riotinto.com/utilities/search/ShowPressRelease.asp?PDFNumber=316&Keywords='iron%20orre'&PDFDocType=P).

Billiton plc, the large London-based mining and metals company, bought a 2.1% indirect interest in CVRD. The $327 million deal, Billiton's first venture in the iron ore industry, bought the company a 66.97% share in Sweet River Investment Ltd., provided Billiton with 7.74% share in Valepar SA. Valepar was established in 1997 to participate in the privatization of CVRD by the Brazilian Government and holds a 27% interest in CVRD and a 42% voting interest, which effectively made them the controlling shareholder. The transaction gave Billiton a seat on Valepar's executive board (Kepp, 2000d; Kohl, 2000; Mining Journal, 2000a).

On May 11, CVRD purchased Mineração Socoimex S.A. (Socoimex) whose main iron ore mine, the Gongo Soco Mine is located along the CVRD-owned Vitoria Minas railroad. The mine reportedly has proven reserves of 75 Mt of high-grade hematite and 30 Mt of itabirite. Socoimex has been producing 7 Mt/yr of sinter seed, pellet feed, and lump ore for the domestic market and Europe (Metal Bulletin, 2000g; TEX Report, 2000d; Companhia Vale do Rio Doce, May 15, 2000, CVRD acquired SOCOIMEX, accessed August 24, 2000, via URL http://www.cvrd.com.br/ing/infofin/e_infofin.htm).

On May 30, CVRD purchased 63% of S.A. Mineração Trinidade - Samitri (Samitri) from the Luxembourg-based Arbed Group. The sale was part of Arbed's plan to focus on its core steelmaking business, through the divestment of noncore assets. In September, CVRD made an offer to the minority shareholders, which resulted in the acquisition of 36% of the remaining shares, raising CVRD's ownership of Samitri to 99%. Samitri owned four mines in Minas Gerais, as well as 51% of Samarco Mineração S.A., with BHP holding the remaining 49%. BHP and CVRD agreed to enter a joint venture to rationalize the Alegria Iron Ore Complex in Brazil. The companies agreed that BHP would acquire a further 1% holding in Samarco to equalize its ownership with Samitri at 50-50. Samitri and Samarco have iron ore mining and processing facilities in the Alegria Complex. The agreement between BHP and CVRD was to facilitate the restructuring of Samitri and Samarco operations aimed at increased efficiencies, reducing costs, and improving Samarco's product quality.

Samitri's mines, Alegria, Andrade, Corrego do Meio, and Morro Agidu, are in the Brazilian State of Minas Gerais. Prior to the sale of Samitri to CVRD, the Andrade Mine was sold to Arbed's Brazilian steel subsidiary Companhia Siderúrgica Belgo Mineira. Samitri's production capacity is 17.5 Mt/yr. Their products include sinter feed, concentrate, and lump, most of which are moved by rail under contract with CVRD to the port of Tubarão. Samarco's assets include a mine and concentrating plant near Alegria and a pellet plant and port at Ponta Ubu. They are linked by a 396-km slurry pipeline. Samarco recently doubled its pellet production capacity to 12 Mt/yr and plans to invest $126 million through 2002 for a further expansion to 14 Mt/yr. Most of the increased production will be sent to Asia. Part of the investment will be spent on a hydroelectric plant to help make Samarco self-sufficient in energy (Kepp, 2000c; Mining Journal, 2000b; TEX Report, 2000b; Jones, 2001; BHP Ltd., May 31, 2000, BHP and CVRD enter agreement to rationalise the Alegria iron ore complex in Brazil, accessed February 18, 2000, at URL http://www.bhp.com/default.asp?page=62&file=newscentre/pressarchive/20000531a.asp; Companhia Vale do Rio Doce, written commun., November 22, 2000; Companhia Vale do Rio Doce, written commun., March 19, 2001).

On October 9th CVRD through Itabira Rio Doce Co. Ltd., a wholly owned subsidiary, purchased one-half of the 4-Mt/yr pellet plant in Bahrain. CVRD, with joint-venture partner and investment bank Gulf Investment Corp., paid $183 million. The plant has its own port capable of taking ships of 100,000 deadweight tons (dtw), and a thermoelectric powerplant. CVRD already supplies most of the plant's pellet feed. About 75% of the plant's output is for the direct reduction market (Metal Bulletin, 2000f; i; Cia.Vale do Rio Doce, October 6, 2000, CVRD acquires pelletizing plant in Bahrain, accessed February 27, 2001, at URL http://www.cvrd.com.br/ing/e_mapadosite.htm).

CVRD and a group of institutional investors acquired Ferrovia Centro-Atlântica (FCA), the largest railroad in Brazil. FCA has 7,080 km of track and its own fleet of 270 locomotives and 8,400 railcars. It connects the iron ore mines in Minas Gerais to the port of Tubarão [Cia. Vale do Rio Doce, January 24, 2000, Ferrovia Centro-Atlântica (FCA), accessed February 27, 2000, at URL http://www.cvrd.com.br/ing/e_mapadosite.htm].

In the space of 5 months, CVRD acquired the whole of two iron ore producers and one-half of a third. In doing so it has increased its production capacity by more than 30 Mt/yr. It has also increased its jointly held pellet production capacity by 14 Mt/yr, a gain of 56%. Its reserves have increased considerably. The company has solidified its position as the world's largest iron ore producer.

Among the effects of these acquisitions are the following: Two of the three iron ore producers (CVRD and Rio Tinto) became larger; with the third largest (Rio Tinto) becoming the second largest. The consolidations will provide CVRD and Rio Tinto with more leverage in price negotiations. Both companies should be in better positions to reduce costs. A major

Digitized by Google

greenfield project will be developed. Deposits of other companies stand a better chance to be developed. With the big three in Western Australia becoming the big two, deposits such as Hope Downs are more likely to be funded because they could provide competition to Rio Tinto and BHP.

Australia.—(See also earlier section on Mergers and Acquisitions.) BHP announced that it had decided to raise production at its Yandi Mine in the Pilbara region of Western Australia because of continued strong demand for its fines. The company intends to increase production from 25 Mt/yr to 30 Mt/yr. The increase is to be achieved with only minor modifications to existing operations. BHP also intends to introduce a new higher value product: Yandi lump, a pisolitic iron ore. Trial with the Yandi lump began during the year in cooperation with the Japanese steel mills. Four mining campaigns have produced 375,000 t of Yandi lump for shipment to Japan, and BHP has decided to extend the trial mining for another year (Metal Bulletin, 2000a).

In 1999, BHP offered its 1,000 employees at its Pilbara iron ore operations in Western Australia individual staff contracts to replace the existing employee contracts between the company and labor unions. The object of these contracts was to broaden the range and type of work being done by employees to increase productivity (Kirk, 2001, p. 41.4).

Staff contracts have been the norm at competing iron ore producers—at Robe River since the 1980s, and at Hamersley since the mid-1990s (Metal Bulletin, 2000b). The old contracts negotiated with the unions could have put BHP at a competitive disadvantage with the other two major Western Australia iron ore producers. Workers held a one-day strike in December 1999 to protest BHP's tactics, and the labor unrest continued into the new year (Mining Journal, 1999). The Australian Council of Trade Unions began legal action against the company, alleging that BHP's strategy of offering staff contracts was unlawful (Mining Journal, 2000c). The Australian Federal Court issued an injunction on January 31 against BHP, preventing the company from offering and entering into individual contracts with members of its Pilbara workforce. At yearend, the situation remained unresolved.

Strong demand for Marra Mamba type iron ore has heightened the prospects for BHP to develop its Mining Area C (MAC) deposit near the Yandi Mine. Full capacity of 15 Mt/yr at the $80-million project could be reached by 2010, although there is potential to increase production to 20 Mt/yr. A $70-million rail line will link MAC to the Yandi Mine. Another $11 million will be needed to upgrade the rail network that links BHP's mines to its port at Port Hedland. If production is boosted to 20 Mt/yr, BHP would have to use larger locomotives capable of hauling more than 300 railcars compared with 100 currently (Hagopian, 2000).

Hamersley received approval from the Western Australia Government to increase production capacity at the Yandi Mine from 15 Mt/yr to 20 Mt/yr. No major changes to the existing facilities are planned. The capacity increase will be achieved by plant modifications that will allow annual planned operating hours and throughput rates to be increased (Engineering and Mining Journal, 2000). The Hamersley port expansion and upgrade of the existing Parker Point and East Intercourse Island facilities have been substantially completed. The combined capacity has been increased from 55 Mt/yr to 70 Mt/yr (Western Australia Department of Resources Development, [undated], Commissioned projects (for financial year 1999-2000), accessed March 16, 2000, via URL http://www.drd.wa.gov.au/search/index.htm).

Portman Mining Ltd., which changed its name to Portman Ltd., was mining on Cockatoo Island, off the coast of Western Australia (TEX Report, 2000h). Cockatoo Island had been previously mined by BHP. Portman was treating waste stockpiles and producing a concentrate. That operation was closed, and Portman began mining a 1.6-Mt high-grade hematite deposit at the eastern end of the pit that had been covered by infrastructure facilities. The first shipment of ore from the new operation was made on September 10. The guaranteed specifications of the ore are a minimum 68% Fe and maxima of 1.5% silica, 0.75% alumina, and 0.01% phosphorus. The company expects the mine to have a life of 2 years (Metal Bulletin, 2000e, f; Portman Mining Ltd., February 9, 2000, Portman extends Cockatoo Island output, accessed February 10, 2001, via URL http://www.portman.com.au/html/frames.htm).

At the Koolyanobbing Mine, Portman plans to increase production from the current level of 2 Mt/yr to 3.5 Mt/yr in 2001 and to 6 to 8 Mt/yr over the next 5 years. The expansion includes the opening of an additional storage facility at the port at Esperance, which was completed in July 2000, and the delivery of 50 new railcars. An additional 80 ore cars of a new lighter weight design have been ordered to handle the expansion to 3.5 Mt (Metal Bulletin, 2000m, v, x; Portman Mining Ltd., November 3, 2000, Portman moves ahead with next phase of Koolyanobbing expansion, accessed November 20, 2000, via URL http://www.portman.com.au/html/frames.htm; Portman Mining Ltd., March 11, 2000, Government approval received for dredging of Esperance Harbor, accessed November 20, 2000, at URL http://www.portman.com.au/asp/frames.asp?newsItem=43&news Title=ASX+ANNOUNCEMENTS).

A three-stage dredging program at Esperance will allow the full loading of capesize vessels (those too large to transit the Panama Canal) of as much as 180,000 dwt by the third quarter of 2001. The Western Australia Government has committed itself to the construction of a new shiploader and upgrading of the railway system, which will allow Portman to increase annual production to about 5 Mt/yr. The ability to fully load capesize vessels is expected to lower Portman's seaborne freight rates. Portman's plans also include an A$6 million exploration and development program to evaluate its recently acquired Mt. Jackson, Bungalbin, and Windarling deposits north of the Koolyanobbing operation (Metal Bulletin, 2000d).

The Robe River Mining Co. Pty. Ltd. participants approved the construction of a second mine tailings processing plant. The plant is to have a feed capacity of 7.9 Mt/yr, which is higher than that of the existing plant. The processing plant converts material previously regarded as waste to a salable product by removing clay. The plant is expected to increase the mine's reserves, reduce the stripping ratio, and extend the life of the Mesa J operation by 1½ years. The first process plant, which was commissioned last year, has performed at better than planned recovery rates and will receive minor upgrades to increase its feed capacity to 5.2 Mt/yr (TEX Report, 2000c, g; North Ltd., January 16, 2000, Robe ships 500 million tonne, accessed February 15, 2000, at URL http://www.north.com.au/news-releases/rel-2000011700.html).

ABM Mining Ltd., formerly Australian Bulk Minerals, was to have merged with Ivanhoe Mines Ltd. late in the year. ABM bought the Savage River iron ore operation from the Tasmanian Government in 1997. In 1999, ABM produced 2 Mt of pellets

Digitized by Google

and 48,000 t of concentrate. In September, ABM started the fifth production line in the pellet plant, which is expected to raise pellet production to 2.5 Mt/yr. An expansion project is underway that is expected to raise production to 2.95 Mt/y (Mining Journal, 2000e; TEX Report, 2000a).

Brazil.—(See also earlier section on Mergers and Acquisitions.) CVRD announced a budget of $589 million for its iron ore operations for 2000, 63% of its overall budget (Kepp, 2000b; Metal Bulletin, 2000h). Most of the funds ($410 million) were allocated for the construction of the 6-Mt/yr pellet plant located at São Luìs in northern Maranhão State (Metal Bulletin, 2000j). About $285 million was to be spent on the plant itself and $125 million on the mine, railway, and port infrastructure. Construction began in the first half of the year. Although this will be CVRD's eighth pellet plant, it will be the first to use ore from Carajás, which is in the northern system. It will be similar to the southern system in that the ore will be moved by rail from several hundred kilometers inland to a pellet plant at or near a port from which iron ore is shipped. The plant initially will produce DRI pellets. The plant is to be wholly owned by CVRD, and when it reaches full capacity it will increase the capacity of CVRD's two other wholly owned plants and five joint venture plants to 31 Mt/yr. The plant, scheduled to begin production in mid-2002, will use Lurgi Metallurgie technology.

Other funds were to be used to begin increasing capacity at CVRD's Brucutu Mine in Minas Gerais, which currently produces 2 Mt/yr. The mine was expected to begin producing at a rate of 6 Mt/yr by 2005, eventually reaching a capacity of 24 Mt/yr. Another $30 million was to be spent on expanding the Carajás beneficiation plant and adding to the excavator fleet. The beneficiation plant at Carajás is used to wash, crush, and screen the ore. The ore does not need to be concentrated because of its high Fe content of 67%. Funds were to be directed toward the construction of two hydroelectric dams that are expected to lower operating costs. The southern system rail line was to receive funds to purchase new locomotives.

CVRD announced plans to automate the seven pellet plants at Tubarão in the southern system. Although this $23-million project will result in a marginal increase in capacity, its primary goal is to improve pellet quality, reduce production costs by 20 U.S. cents per ton, and cut the pellet rejection rate. The system will be introduced in three stages: first in field instrumentation, including sensors and measures; second in new software to control and supervise the pelletization process; and third in optimizing control of all processes, principally in energy-intensive areas such as ore crushing and pellet induration. The 4-year project will begin with CVRD I and II plants, which are wholly owned by CVRD and are more than 30 years old (Kinch, 2000; Metal Bulletin, 2000d; Companhia Vale do Rio Doce, written commun., March 19, 2001).

Mineraçãoes Brasileiras Reunidas S.A. (MBR) plans to spend $240 million over the next 2 years to increase the company's production capacity from its current 26.5 Mt/yr to 32 Mt/yr. Some of the funds will go into building a new beneficiation plant to handle the increased production from MBR's new mines, Tamandua and Capito do Mato. The production is to offset the production lost when the Aguas Claras and Mutuca Mines are depleted. In addition, the terminal at the port of Septiba will receive a new stacker-reclaimer (Kepp, 2000a).

Canada.—(See also earlier section on Mergers and Acquisitions.) The Board of Directors of IOC announced on June 30 that it had approved the refurbishment and reactivation of its pellet plant in Sept-Iles at a cost of $254 million, some of which had already been spent on engineering and evaluation studies. Closed since 1982, the refurbished plant is expected to be commissioned in June 2002. Initial production rate in the second half of 2002 is expected to be 1.3 Mt, with full production of 4.5 Mt of high-quality blast furnace pellets being achieved in 2003. The pellets will be mainly for North American and European steel mills. This increased production rate is expected to lift pellet production at IOC to 17 Mt/yr and take nearly all of IOC's production through to pellet form.

IOC selected Svedala Industri to supply engineering, equipment, and services for the reactivation of the plant. Svedala Pyro Systems USA, which will provide services throughout the construction and startup phases of the project, has already begun work. IOC also announced that it was to buy 12 new haul trucks for the mine (Metal Bulletin, 2000ab; Mining Journal, 2000f; g; Iron Ore Co. of Canada, June 30, 2000, Iron Ore Co. of Canada announces reactivation of its Sept-Iles pellet plant, accessed March 7, 2001, at URL http://www.ironore.ca/overview_1.htm).

China.—Officials at the State Administration for the Metallurgical Industry (Sami) expected to import about 65 Mt of iron ore in 2000, about 4 Mt more than in 1999. Their target for pig iron production for the year was 111.4 Mt, and their expected domestic production of 240 Mt of iron ore would only yield 73.6 Mt of pig iron because of the low Fe content of Chinese ore. It takes 3.26 t of Chinese ore to produce 1 t of pig iron; thus, China would need to import some 65 Mt of higher yield ore to produce the remaining 37.8 Mt of pig iron (Metal Bulletin, 2000c). A study by Sami concluded that China should invest further in overseas iron ore mines to raise the proportion of imports from Chinese joint-venture mines from the current 12% to 50%.

China is the world's largest steel producer, with output exceeding 100 Mt/yr in each of the past 5 years, but still must import about 10 Mt/yr of steel to meet domestic needs. There are two overseas investments in iron ore: China Metallurgical Import & Export Corp.'s 40% ownership of the Channar Mine in Australia and Shougang Corp.'s 100% ownership of the Marcona Mine in Peru (Metal Bulletin, 2000w).

India.—Arrangements were being made to ship ore from the port of Haldia near Calcutta, and the Government was planning to build a new port at Dhamra, 70 km south of Paradeep in Orissa. Iron ore production costs in India are relatively low, but transportation costs are high. In Goa, the distance from mine to port is 50 km, but other major mines have to transport their ore long distances to the ports for export. The new port at Dhamra will reduce this distance. Once the ore arrives at a port, there are further problems due mainly to poor port handling facilities, according to Indian Ministry of Mines officials. Nearly all leading ports around the world have loading rates approaching 100,000 metric tons per day (t/d). Indian ports achieve a maximum of 40,000 t/d. It was estimated that shipping ore in 300,000-dwt vessels loaded at 100,000 t/d could achieve a total freight savings of $5 per ton (Metal Bulletin, 2000y; Raghuvanshi, 2000b; TEX Report, 2000e).

The State Government of Karnataka decided to extend by a year the work permit given to Kudremukh Iron Ore Co. (KICOL). KIOCL's 30-year mining lease was due to expire on July 24. The company was granted a 1-year work permit so that mining operations could continue. The issue preventing the

Digitized by Google

long-term lease being granted was the State government's designation of a 500-square kilometer park, which includes the mining leases and all of KIOCL's operations. The company was asked to confine its operations to an area of about 1,400 hectares and not the 4,600 hectares that KIOCL had sought. KIOCL's request for a long-term lease of 20 years will await studies of the environmental impact of the mine (Metal Bulletin, 2000s).

Mineral Sales Pvt. Ltd. (MSPL) plans to sell 2.5 Mt of ore in 2000-01. The company plans to increase production at all its mines, to reach 4.5 Mt/yr to 5 Mt/yr of ore by 2003-04. MSPL has been acquiring new mines to aid in this increase (Metal Bulletin, 2000n).

Jindal Vijayangar Steel plans to open its new iron ore mine. The mine is expected to produce about 1.8 Mt/yr of ore, rising to 3 Mt/yr when full production is reached. The ore will feed the company's new 3-Mt/yr pelletizing plant (Metal Bulletin, 2000r).

Construction was started on the second phase of development for Hy-Grade Pellets Ltd., which will add an 8-Mt/yr beneficiation plant and a 267-km slurry pipeline to the existing 3.3-Mt/yr pelletizing plant. Hy-Grade pellets is a joint venture between the United Kingdom-based steel trading group, Stemcor Holdings, and Essar Steel Ltd. of India, on a 51-49 basis, respectively. Essar Steel entered into a 20-year purchase agreement with the new company. Completion of the plant, which is expected to take 14 to 18 months, will enable Hy-Grade to produce pellets with an Fe content of 68.5%, up from the current level of 67%. The company is also considering increasing pellet capacity to 7 Mt/yr. The pellet plant is near the Visakhapatnam Port Trust and has access to mechanized shiploading facilities capable of handling capesize vessels. More than 30 Mt of iron ore fines lying at the mine head in Bailadila will be beneficiated and transported by slurry pipeline to the pellet plant (Metal Bulletin, 2000l; Raghuvanshi, 2000a).

Some of the smaller iron ore mines in the Indian State of Goa may be forced to close because of rising costs and an increasing tax burden, according to industry officials. Miners are challenging a proposal by the Marmugoa Port Trust to raise cargo-related charges by 25% and are criticizing the State's plan to impose a levy on mining to raise funds for environmental restoration of mine sites. Iron ore companies were also facing a demand to pay tax on their exports for the first time. Mining companies in Goa, particularly iron ore producers, which have enjoyed total tax exemptions on their exports since 1991, will have tax on their earnings introduced in a phased manner. In the first year, 20% of their income will be taxed; the rest will be taxed in 20% increments per year for 4 years until all export income is taxed (Metal Bulletin, 2000aa, o, z).

Ten companies, seven of them international firms, responded to an expression of interest for joint-venture participation for mine development with Indian Iron and Steel Co. (Iisco), a wholly owned subsidiary of state-owned Steel Authority of India Ltd. (Sail). The Indian Government announced that it had written off $391 million in loans and advances to Iisco from Sail. Part of the attraction to Iisco is its rich iron ore resources, reportedly measured in billions of tons. The company's Chiria iron ore deposits are the largest in India (Raghuvanshi, 2000c).

Iran.—National Iranian Steel Co. (Nisco), the primary steel producer, set as a goal the production of 7 Mt of steel for 2000, with plans for a further increase to 10 Mt by 2005. Nisco's principal iron ore mine is at Tchogart. It provides at least 5 Mt/yr of lump ore (56% to 60% Fe) to the steelworks at Isfahan. The construction of a new $115-million ore processing plant was proceeding. At Nisco's Gol-e-Gohar Mine, Voest-Alpine Industrieanlagenbau, the Austrian construction firm, is expanding the beneficiation plant to increase capacity from the existing capacity of 3.5 Mt/yr to 5.2 Mt/yr. The project was expected to be completed in 18 months. Elsewhere in the iron ore sector, development is proceeding at the Sangan deposit in eastern Iran, which was expected to produce at an annual rate of 3.4 Mt of concentrates within a few years (Metal Bulletin, 2000p; Mining Journal, 2000g).

South Africa.—The iron ore division of Iscor Ltd. was studying the development of a new mine at a location 60 km south of its existing Sishen Mine. A recent drilling program has shown that the Welgevonden deposit is more promising than had been previously thought and is a potential replacement for the Thabazimbi Mine. Iron ore reserves at Thabazimbi are forecast to be depleted in 2006 to 2007 (Metal Bulletin, 2000t; TEX Report, 2000f).

Venezuela.—CVG Ferrominera Orinoco was expecting iron ore sales to rise to 27 Mt/yr by 2004, with most of the increase coming from the domestic market. This will require Ferrominera to invest in its mines, processing, and transport facilities. The company intends to install 12 Mt of new concentration capacity. This is expected to take place in two stages. Ferrominera was close to selecting a contractor to build the first two of three modules, which are expected to be in place by the second half of 2003. The company also intends to raise its pellet plant capacity to 4 Mt/yr (Metal Bulletin, 2000k).

Outlook

Mergers and acquisitions are expected to cause major changes in the structure of the iron ore industry in the near term. Iron ore prices have been declining for some time and there is no reason to believe that this trend will not continue. (See earlier section on Prices.) Thus, iron ore producers must find ways of making profits other than raising prices. As the producers operate in an increasingly global economy, there will be pressure to reduce production costs; one way of doing this is by mergers and acquisitions. Mergers in the mining industry, however, generally do not have as much potential for synergy as they do in other industries. Mining companies usually cannot share infrastructure because mines cannot be moved. Synergy can be achieved by the industry by the consolidation of corporate and other activities.

The domestic iron ore industry is totally dependent on the steel industry for sales. This dependence is not expected to change in the near future. Information about steel industry trends is provided in the outlook section in the Iron and Steel chapter of the 2000 USGS Minerals Yearbook. For the near term, growth of the U.S. iron ore industry is tied to the growth of the integrated steelworks along the Great Lakes. Significant expansion in the domestic iron ore industry may be possible if one or more direct-reduction processes prove to be economic for existing and potential Great Lakes producers. If this occurs, the industry can supply the rapidly expanding minimill sector of the U.S. steel industry. Steel products require lower residual alloy content than can be readily achieved with scrap. This indicates a role for imported DRI in the coastal regions of the United States and domestically produced DRI further inland where cheaper power is available. However, no matter how

Digitized by Google

spectacular DRI growth is during the next decade, it will not be able to replace more than a fraction of the world's blast furnace production because of technological restrictions. The blast furnace is expected to remain the mainstay of the iron and steel industries in most developed countries during the next 25 years.

Based on recent growth rates in Asia, additional iron ore production capacity will be needed there and in other countries. As in the United States, much of the increase in consumption of iron in Asia will be from newly constructed minimills, but unlike the United States, where the consumption of iron ore in blast furnaces is declining, much of the additional ore needed will go to feed blast furnaces.

TABLE 1
SALIENT IRON ORE STATISTICS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

	1996	1997	1998	1999	2000
United States:					
Iron ore (usable, less than 5% manganese): 2/					
Production	62,083	62,971	62,931	57,749	63,089
Shipments	62,200	62,800	63,200	58,500 r/	61,000
Value	$1,750,000	$1,860,000	$1,970,000	$1,550,000	$1,560,000
Average value at mines, dollars per ton	$28.07	$29.60	$31.14	$26.47	$25.57
Exports	6,260	6,340	6,000	6,120	6,150
Value	$232,000	$235,000	$245,000	$243,000	$246,000
Imports for consumption	18,400	18,500	16,900	14,300	15,700
Value	$556,000	$547,000	$517,000	$399,000	$420,000
Consumption (iron ore and agglomerates)	79,600	79,500	78,200	75,100	76,500
Stocks, December 31:					
At mines, plants and loading docks 3/	4,650	4,860	6,020	5,710	9,150
At receiving docks 4/	2,250	2,880	4,080	2,770	2,860
At consuming plants	18,800	20,200	20,500	17,900	16,800
Total 5/	25,700	27,900	30,600	26,400	28,800
World, production 6/	1,018,436 r/	1,068,727 r/	1,050,688 r/	1,019,051 r/	1,061,148 e/

e/ Estimated. r/ Revised.
1/ Data are rounded to no more than three significant digits, except "Production," and "World, production;" may not add to totals shown.
2/ Direct-shipping ore, concentrates, agglomerates, and byproduct ore.
3/ Excludes byproduct ore.
4/ Transfer and/or receiving docks of Lower Lake ports.
5/ Sum of stocks at mines, consuming plants, and U.S. docks.
6/ Gross weight.

TABLE 2
EMPLOYMENT AT IRON ORE MINES AND BENEFICIATING PLANTS, QUANTITY AND TENOR OF ORE PRODUCED, AND AVERAGE OUT PUT PER WORKER-HOUR IN THE UNITED STATES IN 2000, BY DISTRICT AND STATE 1/

	Average	Worker-	Production (thousand metric tons)				Average per worker-hour (metric tons)		
District and State	number of employees	hours (thousands)	Crude ore	Usable ore	Iron contained in usable ore)	Iron content, natural (percentage)	Crude ore	Usable ore	Iron contained
Lake Superior:									
Michigan 2/	1,700	3,450	45,200	15,000	9,280	61.7	13.12	4.36	2.69
Minnesota	5,100	10,500	162,000	48,000	30,400	63.4	15.43	4.56	2.89
Total or average	6,800	14,000	208,000	63,000	39,700	63	14.86	4.51	2.84
Other States 3/	10	22	55	60	20	34	2.51	2.72	0.92
Grand total or average	6,810	14,000	208,000	63,100	39,700	62.9	14.84	4.51	2.84

See footenotes at end of table.

TABLE 2--Continued

EMPLOYMENT AT IRON ORE MINES AND BENEFICIATING PLANTS, QUANTITY AND TENOR OF ORE PRODUCED, AND AVERAGE OUT PUT PER WORKER-HOUR IN THE UNITED STATES IN 2000, BY DISTRICT AND STATE 1/

1/ Data are rounded to no more than three significant digits, except "Average per worker-hour," and "Crude ore;" may not add to totals shown.
2/ Does not include professional or clerical workers at mine of plant or maintenance shop nor research lab workers.
3/ Includes California and South Dakota.

TABLE 3

CRUDE IRON ORE MINED IN THE UNITED STATES IN 2000, BY DISTRICT, STATE, AND MINING METHOD 1/ 2/

(Thousand metric tons unless otherwise specified and exclusive of ore containing 5% or more manganese)

District and State	Number of mines	Open pit	Underground	Total quantity
Lake Superior:				
Michigan	2	45,200	NA	45,200
Minnesota	8	162,000	NA	162,000
Total	10	208,000	NA	208,000
Other States:	2	55	NA	55
Grand total	12	208,000	NA	208,000

NA Not available.
1/ Excludes byproduct ore.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.

TABLE 4

USABLE IRON ORE PRODUCED IN THE UNITED STATES IN 2000, BY DISTRICT, STATE, AND TYPE OF PRODUCT 1/

(Thousand metric tons and exclusive of ore containing 5% or more manganese)

District and State	Direct shipping ore	Concentrates	Agglomerates 2/	Total
Lake Superior:				
Michigan	39	--	15,000	15,000
Minnesota	406	187	47,400	48,000
Total	445	187	62,400	63,000
Other States 3/	55	5	--	60
Grand total	500	191	62,400	63,100

-- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Data may include pellet chips and screenings.
3/ Includes California and South Dakota.

TABLE 5

SHIPMENTS OF USABLE IRON ORE FROM MINES IN THE UNITED STATES IN 2000 1/ 2/

(Exclusive of ore containing 5% or more manganese)

District and State	Gross weight of ore shipped (thousand metric tons)				Average iron content, natural (percentage)	Value (thousands)
	Direct shipping ore	Concentrates	Agglomerates	Total		
Lake Superior:						
Michigan	43	--	14,200	14,200	61.6	W
Minnesota	299	171	46,300	46,700	63.3	$1,180,000
Total reportable or average	342	171	60,400	60,900	62.9	1,180,000
Other States 3/	109	--	--	109	62.1	2,210
Total withheld	--	--	--	--	--	375,000
Grand total or average	451	171	60,400	61,000	62.9	1,560,000

W Withheld to avoid disclosing company proprietary data. -- Zero.
1/ Includes byproduct ore.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.
3/ Includes California and South Dakota.

TABLE 6
CONSUMPTION OF IRON ORE AT U.S. IRON AND STEEL PLANTS 1/ 2/

(Thousand metric tons)

	Iron ore originating areas					
	U.S. ores		Canadian ores			
Year	Great Lakes	Other U.S.	Great Lakes	Other Canada	Foreign ores	Total
1999	56,900 r/	--	448 r/	5,220 r/	5,420 r/	68,000 r/
2000	57,900	--	343	5,920	6,520	70,700

r/ Revised. -- Zero.
1/ Excludes dust, mill scale, and other revert iron-bearing materials added to sinter.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.

Source: American Iron Ore Association.

TABLE 7
CONSUMPTION OF IRON ORE AT U.S. IRON AND STEEL PLANTS, BY TYPE OF PRODUCT 1/

(Thousand metric tons)

Type of product	1999	2000
Blast furnaces:		
Direct-shipping ore	645	345
Pellets	59,400	61,800
Sinter 2/	10,900	10,600
Total	70,900	72,800
Steelmaking furnaces:		
Direct-shipping ore	48	40
Pellets	24	21
Sinter 2/	172	184
Total	244	245
Grand total	71,200	73,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes briquettes, nodules, and other.

Source: American Iron and Steel Institute.

TABLE 8
U.S. CONSUMPTION OF IRON ORE, BY END USE 1/ 2/

(Thousand metric tons and exclusive of ore containing 5% ore more manganese)

Year	Blast furnaces	Steel furnaces	Sintering plants 3/	Miscellaneous 4/	Subtotal integrated iron and steel plants 5/	Direct-reduced iron for steelmaking 6/	Nonsteel end uses 7/	Total
1999	62,100	57	5,840	2	68,000	2,420	1,290	71,700
2000	64,400	49	6,190	--	70,700	2,340	1,150	74,100

-- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes agglomerates.
3/ Excludes dust, mill scale, and other revert iron-bearing materials.
4/ Sold to nonreporting companies or used for purposes not listed.
5/ Data from American Iron Ore Association.
6/ U.S. Geological Survey estimates based on production reports compiled by Midrex Corp.
7/ Includes iron ore consumed in production of cement and iron ore shipped for use in manufacturing paint, ferrites, heavy media, cattle feed, refractory and weighing materials, and for use in lead smelting. Data from U.S. Geological Survey surveys.

e/ Estimated. p/ Preliminary. r/ Revised. NA Not available. -- Zero.

1/ Table includes data available through July 14, 2001.

2/ Insofar as availability of sources permit, gross weight in this table represent the nonduplicative sum of marketable direct-shipping iron ores, iron ore concentrates, and iron agglomerates produced from imported iron ores have been excluded under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

3/ Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported, except for the following countries for which grades are U.S. Geological Survey estimates: Azerbaijan, Kazakhstan, North Korea, and Ukraine.

4/ In addition to the countries listed, Cuba and Vietnam may also produce iron ore, but definitive information on output levels, if any, is not available.

5/ Reported figure.

6/ Series represented gross weight and metal content of usable iron ore (including byproduct ore) actually produced, natural weight.

7/ Nickeliferous iron ore.

8/ Data are for year beginning March 21 of that stated.

9/ Gross weight calculated from reported iron content based on grade of 60% Fe.

10/ Concentrates from titaniferous magnetite beach sands.

11/ Includes manganiferous iron ore.

12/ Includes magnetite ore as follows, in thousand metric tons: 1996--2,070; 1997--2,564; 1998--2,211; 1999--2,200; 2000--2,854.

13/ Includes byproduct ore.

IRON OXIDE PIGMENTS

By Michael J. Potter

Domestic survey data and tables were prepared by Richelle J. Ellis, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Natural iron oxides are derived from hematite, which is a red iron oxide mineral; limonites, which vary from yellow to brown, such as ochers, siennas, and umbers; and magnetite, which is black iron oxide. Synthetic iron oxide pigments are produced from basic chemicals. The three major methods for the manufacture of synthetic iron oxides are thermal decomposition of iron salts or iron compounds, precipitation of iron salts usually accompanied by oxidation, and reduction of organic compounds by iron (Podolsky and Keller, 1994, p. 765, 772).

Production

U.S. output of finished natural (mined) iron oxide pigments (IOPs) sold by processors in 2000 was 87,800 metric tons (t), about 5% less than in 1999; this category accounted for 51% of the tonnage and 15% of the value of total IOP output. Finished synthetic IOPs were 83,900 t, a decrease of 8% from that of 1999, and accounted for 49% of the tonnage and 85% of the value of total IOP output. Total finished natural and synthetic IOPs were 172,000 t, about 6% less than in 1999 (table 2).

Production data for crude IOPs sold or used were developed from a voluntary survey. Of six known companies, data were obtained from five, for an 83% response rate. By tonnage, the five companies represented about 70% of the output. In a second voluntary survey, data were received from 12 of 14 known operations that produced finished IOPs, for a response rate of 86%. By tonnage, the 12 operations represented 80% of the output.

Data were obtained from three producers of regenerator iron oxide, which is obtained when spent pickle liquor from steelmaking is treated (table 3). Output from the three companies was about 34,500 t of iron oxide. A major end use for this material was ferrites. Regenerator iron oxide data are not included in tables 1, 2, and 4.

Bayer Corp. introduced two new yellow grades of synthetic IOPs, which were geared toward use in standard solvent-based paints and coatings, as well as high solids and water-based paints. One of the pigments was being manufactured at the company's new iron oxide unit at New Martinsville, WV, and the other yellow pigment was being made at Bayer's facility near Sao Paulo, Brazil, specifically for sale in North American markets (Bayer Corp., October 23, 2000, Bayer Corp. introduces two new yellow grades of synthetic iron oxide pigments for use in architectural paints and coatings, accessed June 21, 2001, at URL http://www.bayerus.com/new/2000/10.23.00.html).

Laporte plc announced its intention to sell its pigments and additives companies to K-L Holdings Inc., a company established by Kohlberg Kravis Roberts & Co., L.P. Laporte's Pigments Division comprised IOP companies in the United States and Europe. Markets included construction, coatings, and specialty applications (Industrial Minerals, 2000).

Consumption

The largest end-use categories for total U.S. IOP output (natural and synthetic) in 2000 continued to be construction with 32% and coatings with 22% (table 4).

In New Jersey, a noise barrier concrete wall was installed along a 26-kilometer corridor on interstate highways. Coloring for the entire wall system was a brownish gray (taupe) supplied by Bayer Corp. and was similar to the color of tree trunks surrounding the noise barrier. Changes in reflective light and the varying textures of the wall gave the appearance of three different colors being used (Bayer Corp., May 9, 2000, Color concrete noise barrier walls enhance landscapes along U.S.

Iron Oxide Pigments in the 20th Century

In 1900, U.S. output of natural (mined) iron oxide pigments (IOPs), including ocher, sienna, umber, and "metallic paint" was about 39,000 metric tons with a value of $490,000. "Metallic paint" was red and brown iron oxides produced by grinding the impure mineral in the natural state. Imports of ocher, sienna, and umber were about 5,000 tons. Other major producing countries of ocher were France with 33,100 tons, the United Kingdom with 15,400 tons, and the German Empire with 11,500 tons. In the early 1900s in the United States, natural IOPs were used mostly in linoleum and ready-mixed paints. The other category of IOPs, synthetic, is made by a chemical process, such as the Penniman-Zoph precipitation process, which became commercially important around the 1930s. During World War II, many IOP producers geared their operations more closely to war needs such as olive drab and camouflage paints for military vehicles, artillery, and aircraft. Paint for shipbuilding required large quantities of both natural and synthetic red iron oxide. After the war ended, peace time uses resumed, such as farm buildings, box cars, and domestic construction.

In 2000, total U.S. output of finished IOPs (natural and synthetic) was 172,000 tons with a value of $171 million. The largest end-use categories for total IOP output were construction (such as cement, mortar, and concrete) and paints and coatings. Total U.S. imports of IOPs (natural and synthetic) were 91,300 tons, with China supplying about 48,000 tons, or 53 %, most of which was synthetic material.

interstates, accessed June 21, 2001, at URL http://www.bayerus.com/new/2000/05.10.00html).

Concrete roof tile has made a major appearance throughout the United States during the past 15 to 20 years. Concrete tile roofs initially were found only in the sunbelt areas of Arizona, California, southern Florida, and Nevada because of the strong Spanish and Mediterranean influences. Newer styles have been developed, along with improved installation procedures, and concrete roof tiles have spread to colder areas, including Colorado, Minnesota, Montana, and Utah. Styles available from at least one supplier include flat tile that simulates wood shakes or shingles and smooth slate. Color for the tiles is from numerous shades of black, red, and yellow IOPs. Two or more of these shades are blended to create a wide selection of earth-tone colors, including shades of adobe, buff, and tan. Concrete roof tile strengthens over time; in Europe, where concrete roof tile has been the predominant roofing material for nearly a century, roof tiles can last over 75 years, even in severe weather conditions. The tiles are also fire resistant, and technological advances have enabled the tile to rival the appearance of clay tile (Bayer Corp., October 17, 2000, Colorful concrete roof tile enhances the quality and style of homes throughout the United States, accessed June 21, 2001, at URL http://www.bayerus.com/new/2000/10.17.00.html).

IOPs, especially those with large particle size that maximizes opacity and gives high color strength, have been manufactured since the late 19th century. In the past 40 years, synthetically produced transparent iron oxides have been developed that give and enhance color and protect wood against weathering, fungi, and ultraviolet radiation. The preferred processes for the manufacture of transparent iron oxide involve precipitation and oxidation of iron from a ferrous salt solution. Ferrous sulfate is the preferred salt because it is readily available as a byproduct from the manufacture of titanium dioxide pigment or from the steel pickling industry. In wood stains and furniture finishes, transparent IOPs find applications such as fencing, decks, lawn furniture, siding, cabinetry, and flooring (Wright and McKenna, 2000).

Prices

Yearend 2000 prices, meant to serve as a general guideline, converted to dollars per kilogram, in bags, per truckload, free on board (f.o.b.) warehouse, were synthetic black, $1.85 to $1.96; synthetic brown, $1.83 to $1.94; natural red, $0.65 to $1.10; natural ochre, $0.81; and synthetic yellow, $1.80 to $1.94 (Chemical Market Reporter, 2000). These prices were essentially unchanged from those of 1999.

The average annual Producer Price Index (PPI) for IOPs for 2000 was 174.9, compared with 173.0 in 1999. The PPI measures the average change over time in the selling prices received by domestic producers of IOPs. The base year for the IOP PPI is June 1983 (Bureau of Labor Statistics, June 20, 2001, Producer price index revision—Current series, accessed June 28, 2001, at URL http://stats.bls.gov/sahome.html).

Foreign Trade

U.S. exports of pigment grade IOPs in 2000 were 9,640 t, 30% less than those of 1999 (table 5). The largest recipients were Japan (22%), Mexico (22%), and Germany (15%).

In 2000, U.S. imports of natural IOPs were 7,340 t (tables 6, 7). The 718 t of micaceous iron oxide (MIO) from Belgium and 913 t from the Netherlands in 2000, however, may not belong in this table, because those countries are not known to be suppliers of MIO. This has yet to be verified with the U.S. Census Bureau; if verified, U.S. imports of MIO would drop to 588 t with a value of $463,000. Imports of synthetic IOPs were 84,000 t, 8% higher than those of 1999. The largest amounts of material were supplied by China (57%), Germany (19%), and India (5%). The total value of synthetic IOPs imports was $73.3 million, which was an increase of 6% compared with imports in 1999.

Total U.S. imports of IOPs (natural and synthetic) were 91,300 t, 7% more than in 1999. The total value of the imports was $76.7 million, 5% higher than that of 1999 (tables 6, 7).

Outlook

Consumption of IOPs is related to activity in the automotive, construction, and housing industries. U.S. apparent consumption of IOPs in 2000 (calculated as production plus imports minus exports) was about 254,000 t, about the same as in 1999. Although housing starts in 2000 were estimated to be about 4% fewer than in 1999, growth in IOP demand reportedly has exceeded overall construction market growth because of an increasing preference for concrete products. An example is the roof tile segment of the industry. One area of the paint industry that has shown above average growth is that of architectural coatings. Use of IOPs as a colorant in plastics reportedly has been spurred in part by plastics continually replacing metal and glass in products such as automobiles (Chemical Products Synopsis, 2000).

KYANITE AND RELATED MATERIALS

By Michael J. Potter

Domestic survey data and tables were prepared by John G. Durand, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Kyanite, andalusite, and sillimanite are anhydrous aluminosilicate minerals with the same chemical formula (Al_2SiO_5) but different crystal structures and physical properties. When calcined at high temperatures (in the 1,400° C to 1,500° C range for kyanite and andalusite and 1,550° C to 1,625° C for sillimanite), these minerals are converted to mullite (Al_6SiO_{13}) and silica (SiO_2) (Harben, 1999). Mullite is a refractory material. During calcination, 1 metric ton (t) of aluminosilicate concentrate yields about 0.88 t of mullite. Synthetic mullite is made by heating mixtures of bauxite and kaolin or alumina and silica at about 1,550° C to 2,000° C (Roskill Information Services Ltd., 1990).

In 2000, the United States, at an estimated 90,000 t, continued to be the main producer of kyanite; reported production data are withheld to avoid revealing company proprietary information. South Africa continued as the leading producing country of andalusite, with over 185,000 t. Sillimanite has had limited production; India has supplied most of the world's output with about 12,000 metric tons per year (t/yr) in recent years.

Legislation and Government Programs

The defense national stockpile contained a total of 136 t of kyanite at yearend 2000. This material was being offered for sale on the third Thursday of every month (Defense National Stockpile Center, November 13, 2000, Kyanite, accessed March 13, 2001, at URL http://www.dnsc.dla.mil/kyanite.htm).

Production

Kyanite Mining Corp. operated two open pit mines in Buckingham County, VA, and beneficiated the ore into marketable kyanite. Some of the kyanite was calcined for conversion into mullite. Company data are proprietary, but Dickson (2000) has estimated U.S. output to be about 90,000 t/yr valued at approximately $13.4 million (before any material was converted to mullite), using a value of $149 per metric ton, the lowest value listed in table 1. High-temperature sintered synthetic mullite, made from calcined bauxitic kaolin and known as one of the company's Mulcoa products, was produced by C-E Minerals, Inc., near Americus, GA. Estimated U.S. production was about 40,000 t/yr (Dickson, 2000) valued at approximately $9.7 million, using a value of about $243 per ton. Kyanite prices, both raw and calcined, increased by about 5% early in 2000 (table 1); Mulcoa prices increased by about 4% in the first half of 1999, but there had been no further increases since then (Dickson, 2000).

Piedmont Minerals Co., Inc., in Hillsborough, NC, mined a deposit containing andalusite combined with pyrophyllite and sericite. The company sells products containing blends of the three minerals to refractories and ceramics producers. There was no known U.S. output of sillimanite.

Consumption

Refractories are the largest end use of kyanite, andalusite,

Kyanite and Related Materials in the 20th Century

Kyanite and related materials were not surveyed by the U.S. Geological Survey until 1939 and probably were not mined at the beginning of the 20th century. Test work on spark plug porcelain at the National Bureau of Standards during World War I stimulated a search for natural sources of these minerals. Andalusite was mined in California and in Nevada for spark plug insulators for the automobile industry. Andalusite mined in California from 1922 to 1936 amounted to about 18,000 metric tons. Kyanite was mined at various periods between 1925 and 1986 in California, Georgia, North Carolina, and South Carolina. In 1932, refractory uses of kyanite included boiler furnaces, brass-melting furnaces, cement kiln linings, electric furnaces, and forging furnaces. The largest long-term kyanite output had come from Virginia from around 1940 and continued into 2000. India was a major producer of kyanite, with output ranging from about 16,000 tons in 1946 to about 119,000 tons in 1970. Production then gradually decreased to the 5,000- to 10,000-ton range in the 1990s. Kyanite was mined in Kenya from about 1946 to 1955, reaching a peak production of about 23,600 tons in 1949. Reserves of easily mined massive kyanite boulders were exhausted in 1952.

In 2000, the United States was the leading producer of kyanite, with an estimated 90,000 tons. South Africa, the leading producer of andalusite, had initial production at least as early as 1939, which then generally increased over time, reaching a high of 284,000 tons in 1989. France was the other significant producer of andalusite; activity began in the early 1970s, and annual output in the late 1990s and 2000 was about 65,000 tons. High-temperature refractories had been and continued to be the largest end use of kyanite, andalusite, and sillimanite. The steel industry used an estimated 60% of refractories in general. Other applications for these heat-resistant materials are in high-temperature environments in furnaces, boilers, ladles, and kilns in the metallurgical, glass, chemical, cement, and other industries.

Digitized by Google

mullite, and synthetic mullite in the United States and worldwide. Mullite in refractories increases the fired strength, resistance to deformation under load, and thermal resistivity. Examples include insulating brick, firebrick, kiln furniture, refractory shapes, and monolithic refractories (made of a single piece or as a continuous structure), including castables (refractory concrete), gunning mixes, mortars, plastics, and ramming mixes. The interlocking grain structure of kyanite/mullite also gives much added mechanical strength to other ceramic compositions even when fired at low temperatures during manufacture. This has resulted in increased use of kyanite in sanitaryware, wall tile, precision casting molds, electrical porcelain, and other products.

Sillimanite was not known to be used in the United States in 2000.

Foreign Trade

The United States exported kyanite, mullite, and synthetic mullite to countries in Europe, Latin America, and the Pacific rim. Although the U.S. tariff code does not differentiate between kyanite, andalusite, and sillimanite, 6,230 t out of 6,440 t of total imports in 2000 were from South Africa and were presumed to be andalusite (table 2). There were no known U.S. imports of kyanite or sillimanite in 2000.

World Review

India.—Mining and mineral processing company Bajaj Associates reportedly began producing sintered mullite for use in the refractories industry. The plant, located at Bangalore, had a capacity of 10,000 t/yr. Raw kyanite feedstock, with 35% to 52% alumina, was being mined about 200 kilometers south of Bangalore. The plant was using Bajaj's own technology, including crushing, grinding, and briquetting equipment, and a rotary kiln. Output was around 800 metric tons per month (t/mo) of kyanite fines and 200 t/mo of sintered mullite for local refractory manufacturers (Industrial Minerals, 2000a).

Japan.—The Japanese refractories industry is known to be very technically advanced but was facing some difficult challenges. Production levels of refractories worldwide have fallen; refractory output tonnage in Japan is less than one half that of the mid-1970s. There has been substantial consolidation and restructuring of refractories companies in Europe and the United States in recent years. By contrast, there were still some 66 refractory manufacturers and 89 manufacturing plants in Japan in 1998. Approximately 70% of refractory demand comes from the steel industry, and many refractory producers are partly or fully owned by steel manufacturers and cement companies. There also has been a rise in imports of low-priced refractory finished products, especially from China (Pearson, 2000).

Because of a lack of indigenous mineral resources, most of Japan's refractory raw material supply was imported. With increasingly stringent requirements concerning purity and properties of refractory materials, refractory manufacturers in Japan and worldwide have turned to synthetic minerals, fused minerals in particular. Naigai Ceramics Co., Ltd., was producing 1,000 t/mo of fused mullite, mainly for hot-blast stove refractories (Pearson, 2000).

Turkey.—The Turkish refractories producer Haznedar Ateş Tuğla Sanayii AŞ was to begin production at a new refractories plant in Istanbul. The targeted production level was 50,000 to 60,000 t/yr of high density alumina and magnesia bricks. Raw materials included calcined bauxite, andalusite, and tabular alumina (a well-sintered, high purity, coarse crystalline alpha alumina; the tabular name comes from its hexagonal tablet-shaped crystal composition) (Alcoa World Chemicals, [undated], Products, accessed April 2, 2001, via URL http://www.alumina.alcoa.com/products). Sources of imported raw materials were both local and foreign. About 70% to 75% of the refractories were for local use and the reminder for export (Industrial Minerals, 2000b).

United Kingdom.—Keith Ceramic Materials, Ltd. (KCM), a major producer of fused mullite, was acquired by the Treibacher Schleifmittel AG subsidiary of the French Imerys Group. Treibacher, the world's leading producer of fused alumina, was acquired by Imerys in the first half of 2000. KCM was producing white fused mullite and fused zirconia mullite for use in glass and steel refractories mostly for the European market (Industrial Minerals, 2000c).

Outlook

The largest user of refractories in general in the United States continued to be the iron and steel industry. Raw steel output was about 3% higher than in 1999, according to preliminary data (American Iron and Steel Institute, February 7, 2001, December steel shipments down 17.5% from previous year import surge overshadows 2000 shipment gain, accessed March 8, 2001, at URL http://www.steel.org/news/pr/2001/pr010207_imp.htm). In the steel industry, ladle linings have continued to evolve. Ladle metallurgy has seen increasingly severe operating conditions, such as higher temperature, more chemical attack, and longer exposure time. Brick linings are still dominant in the United States, but the use of monolithics is increasing (Semler, 2000). Advances in steelmaking and other manufacturing processes have resulted in less intensive use of refractories per unit of output produced. Refractories suppliers have been developing products with superior performance and increased longevity, which require less frequent replacement and maintenance. According to Freedonia Group, Inc., opportunity for more growth for refractory products may exist in the petroleum and chemicals market. Of the major refractory forms, monolithic castables and preformed shapes are projected to be the best growth prospects (Ceramic Industry, 2000).

LEAD

By Gerald R. Smith

Domestic survey data and tables were prepared by Richelle J. Ellis, statistical assistant, and the world production tables were prepared by Glenn J. Wallace, international data coordinator.

Domestic lead mine production decreased by about 9% compared with that of 1999. Alaska and Missouri were the dominant producing States with a 91% share. Other appreciable lead mine production was in Idaho and Montana. Lead was produced at 19 mines employing about 1,100 people. The value of domestic mine production was about $440 million. The lead concentrates produced from the mined ore were processed into primary metal at two smelter-refineries in Missouri and a smelter in Montana.

Secondary lead, derived principally from scrapped lead-acid batteries, accounted for 77% of refined lead production in the United States. Nearly all the secondary lead was produced by 7 companies operating 15 smelters.

During 2000, U.S. Government agencies issued several proposed and final rules on matters affecting the lead industry. The rules included issuance of new standards for identifying lead in paint, dust and soil, issuance of new motor vehicle standards to address battery safety in electric vehicles (EVs), revision of regulations for hunting and sport fishing in the National Wildlife Refuge System, and approval of new, nontoxic forms of ammunition for hunting water fowl. In addition, the availability of transition assistance was announced with regard to implementation of the new requirements for notification, evaluation, and reduction of lead-based paint hazards in federally owned residential property and housing receiving federal assistance. A notice of funding availability also was announced in which proposals from Indian Tribes were solicited to conduct blood-lead screening tests on tribal children.

Lead was consumed in about 140 plants to manufacture end-use products, including batteries, ammunition, covering for power and communication cable, building-construction materials, and solders for motor vehicles, metal containers, and electrical/electronic components and accessories.

Lead-acid batteries, including starting-lighting-ignition (SLI) and industrial types, continued to be the overwhelmingly dominant use of lead, accounting for about 87% of reported lead consumption. SLI battery shipments in 2000 totaled 98 million units. This total included original equipment and replacement automotive-type batteries. An estimated 1.04 million metric tons (Mt) of lead was contained in SLI batteries shipped during the year.

Monthly sales of lead from the National Defense Stockpile (NDS) continued during 2000. Sales totaled about 32,000 metric tons (t) (35,300 short tons), leaving about 220,000 t (242,000 short tons) in the NDS at yearend.

Lead prices continued to decline throughout the year. The average London Metal Exchange (LME) and North American Producer prices were down by $0.022 per pound and $0.002 per pound, respectively, in 2000, from the average prices of $0.228 per pound and $0.437 per pound, respectively, in 1999.

Of the 42 countries in which lead was mined, the top 5 accounted for 70% of the world's total production of 3.1 Mt. Australia was the largest producer, with 23% of the world total,

Lead in the 20th Century

In 1900, the United States was the largest producer of refined lead in the world, accounting for about 29% of world production. Other significant producers included Australia, Germany, Mexico, and Spain. Mine production of lead was conducted principally in the States of Colorado, Idaho, Kansas, Missouri, Montana, and Utah, with the Coeur d'Alene mining district in Idaho contributing about 28% of the total production. The demand for lead was essentially in balance with domestic production, necessitating very little reliance on imports. Uses of lead in the United States were primarily for ammunition, brass, burial vault liners, ceramic glazes, leaded glass and crystal, paints or other protective coatings, pewter, and water lines and pipes. The use of recycling as a source of refined lead had begun as early as 1867. By 1900, recycled lead continued to represent a small but undifferentiated portion of the total production of refined lead. In 1907, as further information became available, lead recycling was estimated to represent about 6% of the total production of refined lead in the United States.

In 2000, the United States continued to be a major producer of refined lead, representing about 23% of the total world production. Other major producers of refined lead were Australia, Canada, China, France, Germany, Italy, Japan, and the United Kingdom. Nearly 77% of the U.S. production was derived through recycling. The predominant source of lead scrap for recycling was spent lead-acid batteries. Mine production of lead was conducted principally in Alaska and Missouri. A continuing strong demand for lead, particularly in the battery sector where 87% was used, required that the United States depend on imports and purchases from the U.S. Defense Stockpile for about 22% of its lead consumption. Lead was also consumed in end-use products including ammunition, building construction materials, sheet and oxides for radiation shielding, solders, and automobile wheel weights.

Digitized by Google

followed by China, 18%; the United States, 15%; Peru, 9%; and Mexico, 5%.

Worldwide reserves of lead contained in demonstrated resources from producing and nonproducing deposits at yearend were estimated to be 64 Mt by the U.S. Geological Survey (USGS). Reserves for the three largest producers in the world, Australia, the United States, and China, were about 15 Mt, 6.5 Mt, and 9 Mt, respectively. The reserve base (reserves plus measured and indicated resources that are marginally economic and some of those that are currently subeconomic) for Australia and China was 28 Mt and 30 Mt, respectively. The reserve base for the United States was 20 Mt. The total world reserve base at the end of 1999 was estimated to be 130 Mt.

The USGS has issued a report on undiscovered gold, silver, copper, lead, and zinc deposits in the United States (U.S. Geological Survey, 2000). In the report, the estimate of the amount of lead in undiscovered mineral deposits ranged from greater than 47 Mt (90% probability) to greater than 130 Mt (10% probability). The mean estimate of lead in undiscovered deposits was 85 Mt with nearly one-half thought to be contained in undiscovered sedimentary exhalative deposits. Other major lead deposit types considered in the report were Mississippi Valley and polymetallic replacement deposits. Identified U.S. lead resources were estimated to be 51 Mt. Coupled with an estimated past lead production of 41 Mt, the total discovered lead resource in the United States was estimated to be 92 Mt.

Legislation and Government Programs

Monthly sales of lead from the NDS continued during 2000. As a result of these sales and the delivery of previously committed inventory, lead disposal from stockpile inventory during 2000 totaled about 32,000 t (35,300 short tons). The Defense National Stockpile Center's (DNSC) Annual Materials Plan (AMP) approved by the U.S. Congress for fiscal year 2000 (October 1, 1999, to September 30, 2000) included a maximum sales authority for lead of 54,400 t (60,000 short tons). Under this authority, disposal of lead from NDS inventory during the first 9 months of calendar year 2000 was 24,200 t (26,700 short tons). The AMP approved by the U.S. Congress for fiscal year 2001 (October 1, 2000, to September 30, 2001) also included a maximum sales authority for lead of 54,400 t (60,000 short tons). Under the fiscal year 2001 authority, disposal of lead from NDS inventory during the last 3 months of 2000 amounted to 7,800 t (8,600 short tons), leaving about 220,000 t (242,000 short tons) of lead at yearend. A solicitation was issued by the DNSC in July 2000 for the sale of lead from the NDS in negotiated long-term contracts extending for a contract period of 360 calendar days. This solicitation included several grades of lead totaling about 23,600 t (26,100 short tons).

During 2000, U.S. Government agencies issued several proposed and final rules, announced funding availability, and requested specific information and comments from the public on matters affecting the lead industry. A State Government agency also initiated enforcement of a ban on disposal of certain electronic waste materials containing lead. In February, the U.S. Environmental Protection Agency (EPA) solicited preapplication grant proposals from Indian tribes to conduct blood-lead screening for tribal children and to conduct lead awareness outreach activities for Indian tribes. Grants totaling approximately $2 million were to be awarded to perform these activities and to encourage continuation of these activities in the future. The grants were to be awarded based upon evaluation of the preapplication proposals (U.S. Environmental Protection Agency, 2000a).

In December, the EPA announced new national standards for identifying dangerous levels of lead in paint, dust, and soil. Under these new standards, Federal agencies (including the U.S. Department of Housing and Urban Development (HUD) as well as State, local, and tribal governments) will have new uniform benchmarks on which to base remedial actions taken to safeguard the public from exposure to lead. The standards also will apply to other Federal lead provisions, such as EPA real estate disclosure requirements presently in place for individuals selling or renting a home or an apartment and EPA programs engaged in the cleanup of toxic waste. In addition, the standards will provide landlords, parents, and childcare providers with information on specific lead hazard levels, so that informed decisions can be made on such levels of lead found in homes, yards, or play areas. Under the new standards, lead is considered a hazard if levels are greater than the following: 40 micrograms of lead per square foot in dust on floors; 250 micrograms of lead per square foot in dust on interior window sills; and 400 parts per million (ppm) in the bare soil of children's play areas or 1,200 ppm average in the bare soil in the remainder of the yard. Identification of lead hazards through these standards will allow inspectors and risk assessors to assist property owners in deciding on appropriate processes to correct lead-related problems. These processes may include lead paint abatement, covering or removing lead-containing soil, and professional cleaning of lead dust. The EPA's new standards are in accordance with section 403 of the Toxic Substances Control Act, as amended by the Residential Lead-Based Paint Hazard Reduction Act of 1992, also known as Title X (U.S. Environmental Protection Agency, 2000b).

In August, the EPA issued a notice of availability and solicitation of public comment on the Agency's draft National Action Plan to promote further voluntary reductions of use and exposure to alkyl-lead compounds. Alkyl-lead (e.g. tetraethyl and tetramethyl lead) is used as a fuel additive to reduce "knock" in combustion engines and also to help lubricate internal engine components and protect intake and exhaust valves against recession. Alkyl-lead additives are permitted for use in aviation gasoline for general aviation (piston-engine) aircraft and in fuels for racing vehicles, and nonroad vehicles such as farm machinery, marine vessels, construction equipment, and recreational vehicles. The National Action Plan was developed pursuant to the EPA's Multimedia Strategy for Priority Persistent, Bioaccumulative, and Toxic (PBT) Pollutants (U.S. Environmental Protection Agency, 2000c). The EPA had issued its final rule on the reporting thresholds for certain other PBT chemicals in October 1999 but had excluded any final action on the alkyl-lead compounds in this final rule (U.S. Environmental Protection Agency, 1999).

In September, HUD announced the availability of transition assistance with regard to the implementation of HUD's new requirements for notification, evaluation, and reduction of lead-based paint hazards in federally owned residential property and housing receiving Federal assistance. The new requirements (Lead Safe Housing Regulations) implement Se

Digitized by Google

ctions 1012 and 1013 of the Residential Lead-Based Paint Hazard Reduction Act of 1992, which is Title X of the Housing and Community Development Act of 1992. The final rule on these requirements was issued by HUD in September 1999 with an implementation date effective September 15, 2000. In order to ensure that adequate service providers were available to conduct lead-based paint hazard evaluation and reduction activities safely, effectively, and efficiently under the new requirements, HUD developed a three-component transition assistance policy. The first component authorized a 6-month transition period for program participants in jurisdictions that notified HUD by November 15, 2000, that they lacked the capacity to implement one or more provisions of the Lead Safe Housing Regulation. The second provided a 12-month transition period for post-1960 properties occupied by children under 6 years of age receiving only tenant-based rental assistance. The third component provided a twelve-month transition period for properties receiving Federal rehabilitation assistance greater than $25,000 that are occupied by the elderly, and where no child under 6 years of age resided or was expected to reside. A submission by a jurisdiction was not required in order for participants to be eligible under the second and third components of the transition assistance policy (U.S. Department of Housing and Urban Development, 2000).

In May, the U.S. Department of the Interior, Fish and Wildlife Service, issued its final rule on the 1999-2000 Refuge-Specific Hunting and Sport Fishing Regulations. Under this rule, a revision was made requiring that individuals may possess only approved nontoxic shot while on Waterfowl Production Areas and certain other defined areas of the National Wildlife Refuge System. In addition, in areas where the hunting of wild turkey and deer was permitted, lead-containing shot or slugs could be used unless prohibited by refuge-specific regulations and/or State law. Excluded from the final rule was the establishment of lead-free fishing areas. The Fish and Wildlife Service planned to address this issue in a separate final rule at a later date (U.S. Department of the Interior, 2000d).

In further actions, the Fish and Wildlife Service issued a final rule approving the use of tungsten-matrix shot, and a proposed rule approving tungsten-nickel-iron shot as nontoxic forms of ammunition for hunting waterfowl and coots (U.S. Department of the Interior, 2000a, b). A proposed rule giving temporary approval for the use of tin shot in hunting waterfowl and coots during the 2000-2001 hunting seasons also was issued by the Fish and Wildlife Service (U.S. Department of the Interior, 2000c).

The U.S. Nuclear Regulatory Commission (NRC) amended its regulations in October to add the NAC Universal Storage System (NAC-UMS) to the list of approved spent nuclear fuel storage casks. The amendment allows the holders of power reactor operating licences to store spent fuel in this approved cask system under a general license. Simultaneous with the approval of the NAC-UMS system, the NRC issued a final Safety Evaluation Report and a Certificate of Compliance for the cask system, effective November 20, 2000. Interlocking lead bricks are used in the transfer cask portion of the system. These bricks effectively shield gamma radiation from being emitted from the spent nuclear fuel during loading, unloading, and transfer operations between the transportable storage canister and the vertical concrete cask storage components of the system (U.S. Nuclear Regulatory Commission, 2000).

The U.S. Department of Transportation, National Highway Traffic Safety Administration, issued a final rule in September establishing a new Federal motor vehicle safety standard, FMVSS No. 305, that addresses electrolyte spillage, battery retention, and electrical shock protection in crashes involving EVs. In order to conform to the safety standards, electrolyte spillage of not more than 5 liters will be allowed outside the passenger compartment, and no visible trace of electrolyte will be permitted to spill into the passenger compartment in controlled impact tests. Electrolyte spillage is measured from the moment the vehicle ceases motion following a barrier impact test until 30 minutes thereafter, and throughout any static rollover after barrier impact. Also, no part of the battery component system positioned outside the passenger compartment will be permitted to enter the passenger compartment as a result of the impact. In addition, electrical isolation must be maintained between the battery system and the electrically conductive structure of the EV after impact, such that the electrical resistance is not less than 500 ohms per volt. The final rule applies to all EVs that have a propulsion power source greater than 48 volts and a gross vehicle weight rating of 4,536 kilograms (kg) or less. The final rule will become effective October 1, 2001 (U.S. Department of Transportation, 2000).

In April, the State of Massachusetts began enforcing a ban on the disposal of cathode ray tubes (CRTs) at landfills, transfer stations, and incinerators. The action was taken by the State's Department of Environmental Protection as a measure to prepare for the projected significant increase in the level of CRT disposals in unwanted older televisions and computer monitors. One of the factors considered in the State's concern over the disposal of the CRTs is the environmental consequences of the relatively high lead content associated with them. The lead, an important material in CRTs that protects the consumer from exposure to harmful radiation, is present in CRTs at a level of about 2 to 4 kg. Environmental officials in Massachusetts were hopeful that the ban on discarding CRTs would prompt a strong interest in reuse and recycling of CRT components (American Metal Market, 2000b).

Production

Primary.—In 2000, domestic mine production of lead decreased by about 46,000 t, or 9%, compared with that of 1999. A significant portion of the decline was attributed to planned cutbacks in production at several mines in Missouri. The major share of the U.S. mine output of lead continued to be derived from production in Alaska and Missouri. Appreciable lead mine production also was reported in Idaho and Montana. Domestic mine production data were collected from a voluntary survey on lode-mine production of gold, silver, copper, lead, and zinc by the USGS. All lead-producing mines responded to this survey. The lead concentrates produced from the mined ore were processed into primary metal at two smelter-refineries in Missouri and a smelter in Montana (tables 1-4).

The Doe Run Resources Corp., St. Louis, MO, produced primary lead at two smelter-refinery facilities in Missouri. Concentrates for the smelter-refineries were provided from six Doe Run mills that were supplied with ore mined from eight

Digitized by Google

production shafts along the Viburnum Trend in southeastern Missouri. In addition, concentrate for the smelter-refineries was purchased in the open market. The open market purchases served to supplement Doe Run's announced reductions in mine production in January and April. As of October 31, 2000, the company's proven and probable U.S. ore reserves were about 58 Mt, grading 5.78% lead, 1.25% zinc, and 0.23% copper. In fiscal year 2000, ending October 31, 2000, Doe Run shipped about 510,000 t of refined lead and lead alloy products, including recycled lead produced at its secondary smelter in southeastern Missouri. Doe Run's issued and outstanding stock are indirectly owned by The Renco Group, Inc., a New York-based, privately held company with investments in natural resources and industrial operations. During 2000, the company continued exploration drilling in the vicinity of all eight of its mines in the Viburnum Trend region. Exploration activity was carried out both at the surface and underground, with an intent to delineate additional ore reserves. Drilling also was carried out within most of Doe Run's mines to access ore beyond the current mining areas (Doe Run Resources Corp., 2000, p. 1-7; Metal Bulletin, 2000a, b).

ASARCO Inc., a wholly owned subsidiary of Grupo Mexico, S.A. de C.V., continued to operate the custom primary lead smelter in East Helena, MT, during the year. By midyear, the quantity of lead bullion sold from smelter production was about 32,600 t, an increase of about 8% compared with the same period in 1999 (Grupo Mexico, S.A. de C.V., 2000).

Cominco Alaska Inc., a wholly owned subsidiary of Cominco Ltd., Toronto, Canada, operated the Red Dog zinc-lead mine in northwestern Alaska under a leasing agreement with NANA Regional Corp., the sole owner of the property. NANA is a corporation organized under the provisions of the Alaska Native Claims Settlement Act. The average mill recovery of lead at Red Dog was 58% in 2000, compared with 59% in 1999. Overall production of lead concentrate decreased by 8% to about 140,000 t at an average concentrate grade of 59.6% lead. Delineation drilling during the year outlined the underground Anarraaq deposit that was discovered in 1999 about 10 kilometers northwest of Red Dog. Anarraaq is estimated to contain an inferred resource of 17.2 Mt grading 15.8% zinc and 4.8% lead. A second area of mineralization also was discovered near Anarraaq during the year and, in addition, gravity surveys and borehole geophysics further identified several new target areas of mineralization. The five deposits at Red Dog's mineralized center (Main Zone, Aqqaluk, Paalaaq, Qanaiyaq (formerly Hilltop), and Anarraaq) were estimated to contain total resources of 148 Mt of ore grading 16.6% zinc and 4.5% lead. A major program of in-fill drilling and metallurgical tests conducted on the Aqqaluk deposit during 2000 resulted in the reclassification of some of the Aqqaluk mineralization to the probable reserve category. Proven ore reserves at Red Dog (Main Zone) in 2000 were estimated to be 41.9 Mt grading 19.2% zinc and 5.2% lead. Probable reserves at Aqqaluk were estimated to be 56.1 Mt grading 16.6% zinc and 4.1% lead. In other developmental activities during the year, Cominco, in cooperation with the U.S. Army Corps of Engineers, continued their 2-year study to determine the viability of upgrading Red Dog's existing shipping facility into a deep-water port. The study is addressing the feasibility of dredging a deep channel through the shallow coastal waters to the shoreline in order to accommodate ocean-going vessels, thus permitting direct loading of the concentrate onto ships. The study is due to be completed in 2001 (Cominco Ltd., 2000a, p. 11-22).

Cominco also continued the development of the Pend Oreille zinc-lead mine near Metaline Falls, WA. In September, the Board of Directors of Canada's Cominco Ltd. endorsed the decision made by the Board of Directors of Cominco American Inc., a wholly owned subsidiary of Cominco Ltd., to rebuild the mill and reopen the mine. The 2-year construction project began in October 2000 and involved refurbishment of the existing concentrator, sinking of an internal mine shaft, and conducting other mining preparation activities. Production from the mine is scheduled to begin in September 2002 and is expected to yield 84,000 metric tons per year (t/yr) of zinc concentrate and 13,000 t/yr of lead concentrate. The concentrates will be shipped to Cominco's nearby Trail, B.C., facility for further processing. Cominco officials anticipate that the Pend Oreille Mine will have a minimum life of 10 years and will provide employment for about 170 people (Cominco Ltd., 2000b).

Hecla Mining Co., Coeur d'Alene, ID, operated the Lucky Friday Mine in Mullan, ID, throughout 2000. Lucky Friday is an underground silver-lead mine 100% owned by Hecla that has been a producing mine for Hecla since 1958. A second full year of production was carried out at the adjacent Gold Hunter ore body, effectively increasing lead production by 15.7% to a level of 29,000 t. Ore was processed during the year in a conventional flotation mill at a full-capacity rate of about 1,000 metric tons per day (t/d). Both silver-lead concentrates and zinc concentrates were produced at the mill, with 94% of the silver, 93.6% of the lead, and 41.4% of the zinc being economically recovered. In the fourth quarter of 2000, Hecla recorded a financial adjustment to the Lucky Friday Mine, thereby reducing the carrying value of mine property, plant structures, and equipment. The adjustment was necessitated by continuing low silver and lead prices. In addition, as a result of the low metal prices, Hecla's Board of Directors deferred a decision in the fourth quarter of the year to approve the additional capital expenditures that were needed to carry out development of another area of the mine. Total proven and probable ore reserves at the Lucky Friday and the Gold Hunter deposits were about 1.2 Mt grading 10.7% lead at yearend 2000 compared with 1.5 Mt grading 9.6% lead at yearend 1999.

Hecla Mining also held a 29.7% interest in the Greens Creek Mine on Admiralty Island, near Juneau, AK, through a joint-venture arrangement with Kennecott Greens Creek Mining Co., the manager of the mine, and Kennecott Juneau Mining Co., both wholly owned subsidiaries of Kennecott Corp. At Greens Creek, about 1,500 t/d of ore was mined from the underground 200 South, Southwest, and West ore zones and milled on-site to yield lead, zinc, and bulk concentrates, as well as a gold-silver doré. Total production of lead in concentrate was about 22,800 t in 2000 compared with about 23,100 t in 1999. Estimated reserves at the Greens Creek Mine at yearend 2000 were 9.1 Mt grading 4.4% lead. Drilling continued during 2000, serving to essentially replace the quantity of reserves depleted through production during the year (Hecla Mining Co., 2000, p. 6-12).

Secondary.—Domestic secondary production increased about 2% in 2000. Secondary lead accounted for 77% of domestic lead refinery production compared with 76% in 1999. Lead

Digitized by Google

recovered from scrap lead-acid batteries continued at a high level and accounted for 90% of all lead produced from secondary sources. The domestic secondary statistics were derived by the USGS from a combined secondary producer and consumer survey that included data from monthly and annual surveys. All of the 18 companies producing secondary lead, exclusive of that produced from copper-based scrap, were surveyed; 16 responded, representing more than 99% of the total production of secondary lead. Of the total lead recycled in 2000, about 98% was produced by 7 companies operating 15 plants in Alabama, California, Florida, Indiana, Louisiana, Minnesota, Missouri, New York, Pennsylvania, Tennessee, and Texas. Production and consumption for the nonrespondents were estimated by using prior-year levels as a basis (tables 1, 5-9).

Exide Corp., Reading, PA, completed its acquisition of GNB Technologies, Inc., Atlanta, GA, on September 29, 2000. As a result of the purchase, and following shareholder approval, Exide Corp. was renamed Exide Technologies. GNB had supplied a significant portion of the industrial batteries used in the North American market. Thus, the purchase allowed Exide to reenter the North American industrial battery business. GNB also was a leading supplier of automotive batteries for both the original equipment and replacement battery markets. Following the acquisition, Exide also announced several initiatives designed to restructure the newly formed company: consolidation of automotive battery manufacturing facilities in the United States; consolidation of industrial battery operations in Europe; closure of several distribution centers and branch locations by the end of 2000; and downsizing and relocation of new headquarters to Princeton, NJ, from Reading, PA (Exide Technologies, 2000).

In January, Johnson Controls, Inc., Milwaukee, WI, signed new tolling agreements to recover lead from spent lead-acid batteries for its battery business on the west coast of the United States. Reportedly, the processing of the spent battery units was to be divided between the secondary smelter plants of RSR Corp. at City of Industry, CA, and GNB Technologies, Inc. at Vernon, CA. The tolling agreements were expected to be in effect for 1 year (Ryan's Notes, 2000).

Consumption

Reported consumption of lead increased by 2% as the demand for lead in storage batteries continued to increase. The demand for lead declined in a number of other end uses, including bearing metals, cable covering, and construction materials, such as caulking lead, pipes, traps, and other extruded products. Consumption of lead in SLI- and industrial-type lead-acid storage batteries represented 87% of the total reported consumption of lead. Industrial-type batteries included stationary batteries (such as those used in uninterruptible power-supply equipment for hospitals, computer and telecommunications networks, and load-leveling equipment for commercial electrical power systems) as well as traction batteries (such as those used in industrial forklifts, airline ground equipment, and mining vehicles). Of the 108 consuming companies to which a USGS survey request was sent, 83 responded, representing about 96% of the total reported U.S. lead consumption.

The Battery Council International reported SLI-type battery shipments of 98 million units in 2000 compared with 100 million units in 1999 (Amistadi, 2001, p. 12-31). The totals included original equipment and replacement automotive-type batteries. By using an estimate of 10.6 kg (23.3 pounds) of lead per unit, the SLI shipments in 2000 accounted for about 1.04 Mt of lead. SLI batteries included those used for automobiles, buses, trucks, tractors, motorcycles, and marine craft. (tables 6-13).

World Review

World production of refined lead increased to 6.46 Mt in 2000 from 6.13 Mt in 1999. Other statistics for 2000, as reported by the International Lead and Zinc Study Group, are as follows: world consumption increased to 6.46 Mt from 6.24 Mt in 1999; commercial stocks of refined lead in industrialized countries were 421,000 t, or 4 weeks of consumption, at yearend 2000 compared with 472,000 t at yearend 1999 and 418,000 t at yearend 1998; and significant exports of refined lead to industrialized countries from developing Asian countries, notably China, continued during 2000, increasing by about 10%, to 628,000 t, compared with those of 1999 (International Lead and Zinc Study Group, 2001, p. 6-21).

Lead prices exhibited a declining trend for the fourth consecutive year. The average LME and North American Producer prices were down by $0.022 per pound and $0.002 per pound, respectively, in 2000, from the average prices of $0.228 per pound and $0.437 per pound, respectively, in 1999.

The structure of the lead mining and refining industries was affected by a number of changes, including the opening and development of new facilities, as well as the closing, reopening, expanding, selling, and modernizing of existing facilities (tables 14, 15).

New Mines, Plants, Properties, Resources.—Ireland's Lisheen lead-zinc mine in County Tipperary Ireland was officially opened in late June (Mining Journal, 2000e). By yearend, the mine was being operated at about 70% of capacity. Lisheen was expected to reach full production capacity in the second quarter of 2001, yielding 300,000 t/yr of zinc concentrate and 40,000 t/yr of lead concentrate over a mine life of 14 years. During the first half of 2000, about 58,000 t of zinc concentrate and 19,000 t of lead concentrate were produced at Lisheen. The Lisheen mining operation is a 50-50 joint venture between Ivernia West plc and Anglo American plc in which Anglo American's subsidiary, Anglo Base Metals Ltd., operates the mine (Platt's Metals Week, 2000d).

Canada's Minco Mining and Metals Corp. and Teck Corp. continued a drilling program at the White Silver Mountain polymetallic property in China. Drilling results disclosed in March showed lead contents of up to 10.0%. Earlier drill results had revealed mineralization containing between 3.9% and 4.4% lead. During the remainder of the year, the joint-venture partners developed further the underground region of mineralization to permit additional exploration drilling and also conducted a surface geophysical program (Mining Journal, 2000b).

Canada's Noranda Inc. proceeded with a full feasibility study in May on the development of the Lady Loretta zinc-lead-silver deposit in Queensland, Australia, through its Australian

Digitized by Google

subsidiary Noranda Pacific. Noranda had an option to acquire a 75% interest in the Lady Loretta project from Melbourne-based Buka Minerals Ltd., and had been actively exploring the deposit since early 1999. A decision by Noranda to complete the full feasibility study prior to the option expiration date suggested that development of the Lady Loretta deposit was likely to occur. A drilling program completed by Noranda in the first quarter of the year reportedly indicated a significant increase in the resource estimate at Lady Loretta. Prior to the option agreement the identified resources were 8.2 Mt, averaging 17.6% zinc, 8.4% lead, and 122 grams per ton silver. Although the deposit is very high grade, its development has been hindered thus far by the extremely fine-grained characteristic of the ore that has made it difficult to process using conventional technology (Metal Bulletin, 2000k).

In June, Exide Corp., Reading, PA, announced plans to construct a lead-acid battery manufacturing facility in Bawal, India. The plant, located in the State of Haryana, will be used to manufacture batteries for export, with sales targeted mostly in Southeast Asia through Exide's subsidiary, Chloride Batteries Co. in Singapore. The latter company's strategic partner, Shin Kobe Electric Co., has expressed interest in sourcing battery supplies from India, which would benefit the Exide project (Metal Bulletin, 2000d).

EuroZinc Mining Corp., Vancouver, Canada, reported positive results from a feasibility study completed in June on its Aljustrel project in southern Portugal. Results of the study indicated that about 65,800 t of zinc, 15,400 t of lead, and an appreciable quantity of silver could be produced annually over the first 9 years of operation at Aljustrel's Feitas and Moinho deposits. Aljustrel had operated for several years in the early 1990s. However, low recoveries and inefficient mining methods, combined with low metal prices, forced the closure of the mine. Since that time, the mill and related facilities have been maintained in good condition. With most infrastructure already in place, mine production at Aljustrel could begin as early as the fourth quarter of 2001, with initial feed to the mill coming from the Moinho deposit (Northern Miner, 2000a).

In July, Canada's Vancouver-based Expatriate Resources Ltd. completed the initial process metallurgy and concentrate marketing stages for its Finlayson project in Yukon Territory. The project combines development of the recently acquired Kudz Ze Kayah deposit and the Wolverine deposit, the latter being 40% owned by Atna Resources Ltd. Flotation test results confirmed that ores from Kudz Ze Kayah and Wolverine can be combined to yield improved flotation results over those obtained using only the Wolverine ore as feed material. Based on assessments of a combined mill feed of 4,250 t/d, production of about 200,000 t of zinc concentrate, and 33,000 t of lead concentrate, each containing 55% of the respective metal, were considered possible per year. A prefeasibility study completed at the end of the year outlined probable reserves of 14.6 Mt at Finlayson, grading 7.2% zinc, 1.5% lead, and significant quantities of copper, gold and silver (Mining Journal, 2000d; Northern Miner, 2000b).

Apex Silver Mines Ltd., Denver, CO, received initial assay results in midyear from a drilling program at its Platosa lead-silver-zinc property in central Mexico. The intersection of massive and semimassive sulfide mineralization revealed lead concentrations ranging from 3.6% to 25.2% and zinc concentrations ranging from 0.1% to 17.6%. Apex, through its Mexican subsidiary Mineras de Cordilleras S.de R.L. de C.V., owns a 65% interest in Platosa. Also, Apex reportedly was in the process of increasing its land holdings in the Platosa region where it also owns the adjacent Saltillera property (Mining Journal, 2000g).

In November, Canada's Vancouver-based International Annax Ventures, Inc. (IAV) received assay results from its drilling program at the Sopokomil polymetallic deposit, part of the Dairi property in northern Sumatra, Indonesia. Drilling results showed the intersection of both massive sulfide and carbonate-hosted Mississippi Valley-type mineralization with lead concentrations ranging from 8.4% to 15.2% and zinc concentrations ranging from 6.7% to 23.3%. Australia's Perth-based Herald Resources Ltd. holds a 71% undiluted capital interest in IAV, and was manager of Dairi until May 2000. At that time, Cominco Ltd. began management of the property in accordance with an agreement to earn a 40% interest in the property from IAV in exchange for a 5-year monetary investment in the property (Mining Journal, 2000c, h).

In August, Australian base metals miner MIM Holdings Ltd. reported that its 70%-held McArthur River zinc-lead-silver mine achieved a record production of about 117,000 t of zinc and 30,000 t of lead in concentrate in the 1999-2000 fiscal year. In addition, Mount Isa's output of lead contained in lead-silver bullion was up 7% to a level of 137,000 t compared with the previous fiscal year. MIM also reported that its George Fisher zinc-lead-silver mine at Mount Isa was on target for commissioning within budget by October 2000 (Platt's Metals Week, 2000f).

Australia's Pasminco Ltd. reported the first shipment of lead concentrate from its Century Mine in mid-August. According to Pasminco, shipments of lead concentrate were to proceed on a regular basis and were expected to reach 40,000 t by the end of the year. The company was in the process of progressively increasing its annual production to the full capacity of 880,000 t/yr of zinc concentrate and 70,000 t/yr of lead concentrate. Full production levels were anticipated by the end of 2001 (American Metal Market, 2000a).

Malaysia's Metal Reclamation Bhd began commissioning its new secondary lead smelter near Kuala Lampur in September. According to a company official, Metal Reclamation will continue to target an output of 40,000 t/yr from its existing plant, up 10,000 t from that produced in 1999. The new plant will boost the company's total production capacity to 110,000 t/yr. Metal Reclamation is mainly a processor of secondary lead and a producer of lead alloys (Platt's Metals Week, 2000e).

Denver-based Solitario Resources Corp. reported in December that its joint-venture partner Pasminco Ltd. had completed their 2000 drilling program at the Bongará zinc-lead property in northern Peru. Canada's Cominco Ltd. presently owns a 65% interest in Bongará. Assay results from drilling completed in the Florida Canyon area revealed zinc concentrations ranging from 3.4% to 15.8% and lead concentrations ranging from 2.1% to 12.4%. Pasminco was accorded the right to earn Cominco Ltd.'s 65% interest in Bongará by fully funding the 2000 drilling program and by contributing additional funds for future exploration as part of its overall commitment to the project. Solitario holds a 35% interest in Bongará (Mining Journal, 2000a).

Digitized by Google

In November, Russia's Urals Mining and Metallurgical Co. (UGMK) reportedly was preparing to expand its metals operation to include production of lead and zinc. UGMK, formed a year ago to unite upstream and downstream copper producers in the Urals region into one of Russia's largest metal groups, plans to recover the lead and zinc from byproducts of several of the company's subsidiaries, including the Sredneuralsk copper plant, and the Krasnouralsk and Svyatogor blister copper smelters. Lead and zinc production will be distributed across three sites: Uralelectromed copper refinery, Kirovgrad Metallurgical Co., and the Upper Neivinsk non-ferrous plant. The full production system for lead and zinc is scheduled to be commissioned by September 2001. The principal source of raw material will be metallurgical dust and coke that result from processing copper concentrate and scrap at UGMK's plants. These byproducts can contain between 20% and 25% lead. It is expected that up to 12,000 t/yr of electrolytic lead will be recovered from the copper byproducts when the full production system is in operation (Metal Bulletin, 2000m).

Closings and Curtailments.—In April, Australia's Western Metals began the closure of its Hellyer Mine in Tasmania owing to the depletion of reserves at the mine. Processing of the mined ore was completed in June, at which time the facilities were placed on care-and-maintenance status. Operations at the Hellyer Mine yielded 20,400 t of zinc and 7,600 t of lead in concentrate during the first quarter of the year (Metal Bulletin, 2000n).

China's Shenyang primary lead smelter in Liaoning Province was declared bankrupt in early August as a result of prolonged financial difficulties, according to an official from the Shenyang Minmetals trading company. The Shenyang smelter has a capacity of 60,000 t/yr of refined lead but was operated below its capacity in the first 7 months of 2000 owing to financial constraints that limited the quantity of feedstock the company could purchase. Shenyang smelter officials reportedly were seeking a buyer for the facility immediately following the declaration of bankruptcy (Platt's Metals Week, 2000a).

In Kosovo, international peacekeepers closed the Zvecan primary lead smelter near Mitrovica in mid-August as a result of concerns regarding excessive emissions of lead into the environment. The smelter, part of the Trepca mining complex, was to be placed under the control of the United Nations (UN) following the closure. According to a UN official, the closure was a temporary measure that would allow a French, Swedish, and U.S. consortium, ITT Kosovo, to begin construction that would bring the facility up to environmental standards (Platt's Metals Week, 2000g).

Reopenings and Expansions.—Boliden Apirsa S.L., a subsidiary of Canada's Boliden Ltd., resumed full operation at its Los Frailes Mine near Seville, Spain, in March 2000, producing at a rate of 125,000 t/yr of zinc and 48,000 t/yr of lead contained in concentrates. Los Frailes had been forced to close in April 1998 when a tailings dam failed, flooding a significant portion of the neighboring land. The mine was restarted in June 1999 after its milling license was restored by the local administration, along with a permit to dump tailings in the adjacent Aznalcollar open pit mine (Metal Bulletin, 2000e). In October, however, Boliden Ltd. reported that its subsidiary would not invest in any further development of the open pit operations at Los Frailes and filed for the equivalent of Chapter 11 bankruptcy protection, citing appreciable financial losses since resuming operations (Mining Journal, 2000f). By yearend, Australia's Murchison United NL had entered into an agreement with Boliden Apirsa S.L. to undertake due diligence at the Los Frailes Mine. According to a Murchison spokesperson, it would be necessary to expand the open pit mine in order to access further resources and thus keep the mine in operation for an additional 10 years. Murchison planned to use its due diligence commitment to assess the extent of restructuring and the required investment to achieve this operational goal (Metal Bulletin, 2000j).

In February, Australia's Western Metals Ltd., announced plans to expand the ore processing capacity at its Pillara lead-zinc mine in the Kimberley region of Western Australia. The expansion from the existing level of 1.5 Mt/yr to a level of 2.4 Mt/yr of ore processed will effectively consolidate and reduce the cost of Western's processing operations. Expansion of the Pillara facilities was expected to be completed by January 2001 and more than compensate for the loss of production at the soon-to-be-closed, aging concentrator at Western's nearby Cadjebut Mine (Metal Bulletin, 2000o).

Israel's Hakurnas, a secondary lead producer near Ashdod, proceeded with its expansion plans to increase the quantity of lead-acid batteries recycled. According to a company spokesperson, the move to expand was made in response to the increase in demand for lead by automotive battery producers in Israel and other parts of the Middle East, as well as to the projected increase in demand for lead-acid batteries in electric vehicles during the next 10 years. The increase in secondary lead production resulting from the expansion was expected to be realized in the fourth quarter of 2000. Israel's stringent battery collection system supports the recycling of 95% of the lead consumed in the manufacture of batteries. Thus, much of the supply of spent lead-acid batteries for the Hakurnas operation was expected to be derived from domestic sources (Metal Bulletin, 2000g).

In China, plans to increase lead production were reported by several companies. The Yuguang Gold and Lead Group reported that refined lead production in 2000 was about 78,000 t, exceeding its original target by 8,000 t. Yuguang continued to construct new production facilities and, upon completion, anticipated an additional output capacity of 20,000 to 30,000 t by midyear 2001. Yuguang's refined lead exports in 2000 were about 30,000 t, nearly 10,000 t above the level exported in 1999 (Platt's Metals Week, 2000b). China's Jiyuan Gold Smelter in Henan Province began its 50,000-t/yr lead expansion project and expected to complete the project by the end of 2001. According to a company spokesperson, production at the primary lead smelter was officially scheduled to begin in early 2002. Upon completion of the expansion project, Jiyuan's capacity for production of refined lead will be raised to 120,000 t/yr (Platt's Metals Week, 2000c). Refined lead production at China's Hunan-based Shuikoushan Mining Authority reached 50,000 t in 2000, up appreciably from the levels of the previous 2 years. The company reportedly was considering renovation plans that would nearly double Shuikoushan's current lead production, but a firm schedule had not been set for initiating the 2- to 3-year renovation project (Platt's Metals Week, 2000h).

Digitized by Google

Production at Romania's Sometra zinc-lead primary smelter in Copsa Mica reached a total of 75,000 t in 2000. Lead production represents about one-third of the total production at Sometra. Production levels at Sometra have nearly doubled since its privatization 2 years ago when production was less than 40,000 t/yr. Sometra is now 88% owned by Greek base metals producer Mytilineos Holdings S.A., which has confirmed its long-term commitment to the progress of Sometra through continued modernization and environmentally related improvements. According to a spokesperson for Sometra, a recent decision by the Romanian Government to grant the Copsa Mica area a special status to encourage investment will assist further the modernization process (Metal Bulletin, 2000l).

Transfers of Ownership, Sales Offerings, Mergers.—In September, Eco-Bat Technologies plc, a principal European lead-acid battery manufacturer, agreed to purchase Exide Technologies' Gast secondary lead smelter in Pont-Sainte-Maxence, France. Exide had purchased the Gast facility from Paris-based Cie Européene d'Accumulateurs SA in 1995, but had decided in early 2000 to sell the Gast smelter as part of a move to scale down its global operations. According to an Eco-Bat spokesperson, environmental issues had been resolved at the Gast facility and an extension of the required environmental permit had been received from the French Government. A new furnace also was installed at the facility, increasing the production capacity to 35,000 t from the previous 25,000 t (Metal Bulletin, 2000c, f).

In April, the Privatization Agency of Bulgaria (BPA) reported the receipt of one bid for the purchase of an 80% stake in the Kombinat za Czvetni Metali (KCM) primary lead-zinc smelter near Plovdiv. The bid was received from KCM's management through KCM-2000, a separate entity formed so that KCM could participate in its own privatization. According to the terms of the purchase, KCM-2000 would be permitted to extend payments for the smelter over a 10-year period with no payment due during the first year. The BPA had resumed efforts to privatize KCM in March 2000 following a failed attempt to privatize it in August 1999 (Metal Bulletin, 2000i).

In September, Irish miner Ivernia West plc achieved total control of the Magellan lead project in Western Australia through its acquisition of Polymetals Ltd. Ivernia West previously had a 15.7% interest in the project. Results of a pre-feasibility study showed a minable resource at Magellan sufficient to support a 10-year mine life. A drilling program was continued at Magellan and new ore reserves were evaluated throughout the year. It was anticipated that a full feasibility study would be completed by yearend (Metal Bulletin, 2000h).

Outlook

Total world demand for refined lead is expected to rise in 2001 by 2.2% to 6.54 Mt; in the industrialized countries alone, demand is expected to increase by 1.9% to 5.66 Mt. Demand is expected to continue to grow in Asia, rising by 4.2%, and to remain at the same level as during 2000 in Europe. Lead mine output in 2001 is predicted to rise by 1.0% worldwide to 2.99 Mt and by 1.4% in the industrialized countries to 2.29 Mt. The increase in mine output will be principally as a consequence of increases in production in Australia, Ireland, Mexico, and Sweden. Refined lead production is expected to increase by 2.3% worldwide in 2001 to 6.66 Mt, and by 2.7% in the industrialized countries to 5.21 Mt. Contributing to this increase will be projected rises in production in Australia, Canada, India, and the United States, and the commissioning of new capacity in Israel, Malaysia, and the Republic of Korea (International Lead and Zinc Study Group, 2000).

Lead-acid batteries will continue to dominate the demand for lead. The Chicago-based Battery Council International anticipates continued growth in lead-acid battery usage during the next 5 years. U.S. demand for replacement SLI lead-acid batteries is expected to grow at the rate of about 2% per year. Demand for original equipment SLI batteries, however, will be down, at least through 2001, as a result of a significant decline in passenger car and light truck production (Amistadi, 2001, p. 6-10). Demand for industrial-type lead-acid batteries will grow by 5% in 2001. The industrial battery demand will continue to grow at a rate of about 8% per year through the year 2005 for both motive power batteries and large stationary batteries. Growth in the use of the stationary batteries will be driven principally by their increasing need in the infrastructure supporting the wireless telecommunications markets and uninterruptible power supply systems. However, the rate of growth in the demand for industrial batteries will be tempered somewhat through 2005, as telecommunications companies begin to reduce capital expenditures (Cullen, 2001).

Mine production in the United States should remain constant or decline slightly in 2001 as a result of additional temporary production cutbacks at several of the larger facilities. Refined lead production from primary refineries also will decline as a result of temporary production cutbacks (Metal Bulletin, 2001). Secondary production of lead is expected to remain at a level comparable to that of 2000, but could rise by 2% to 3% should weather-related temperature extremes significantly increase the demand for replacement automotive-type batteries.

TABLE 3
LEADING LEAD-PRODUCING MINES IN THE UNITED STATES IN 2000, IN ORDER OF OUTPUT

Rank	Mine	County and State	Operator	Source of lead
1	Red Dog	Northwest Arctic, AK	Cominco Alaska Inc.	Lead-zinc ore.
2	Fletcher	Reynolds, MO	Doe Run Resources Corp.	Lead ore.
3	Brushy Creek	do.	do.	Do.
4	Buick	Iron, MO	do.	Do.
5	Sweetwater	Reynolds, MO	do.	Do.
6	Lucky Friday	Shoshone, ID	Hecla Mining Co.	Silver ore.
7	Viburnum #28	Iron, MO	Doe Run Resources Corp.	Lead ore.
8	Greens Creek 1/	Admiralty Island, AK	Kennecott Greens Creek Mining Co.	Zinc ore.
9	West Fork	Reynolds, MO	Doe Run Resources Corp.	Lead ore.
10	Viburnum #29	Washington, MO	do	Do.
11	Casteel	Iron, MO	do.	Do.
12	Montana Tunnels	Jefferson, MT	Apollo Gold Co.	Zinc ore.
13	Sunshine	Shoshone, ID	Sunshine Mining Co.	Silver ore.
14	Gordonsville	Smith, TN	Pasminco Ltd.	Zinc ore.
15	McCoy/Cove	Lander, NV	Echo Bay Minerals Co.	Gold ore.
16	Galena	Shoshone, ID	Silver Valley Resources Corp.	Silver ore.
17	Balmat	St. Lawrence, NY	Zinc Corp. of America	Zinc ore.
18	Pierrepont	do.	do.	Do.
19	Young	Jefferson, TN	ASARCO Inc.	Do.

1/ Updated to reflect locality name change.

TABLE 4
REFINED LEAD PRODUCED AT PRIMARY REFINERIES IN THE UNITED STATES, BY SOURCE MATERIAL 1/

(Metric tons, unless otherwise specified)

Source material		1999	2000
Refined lead:			
Domestic ores and base bullion		350,000	341,000
Foreign ores and base bullion		W	W
Total		350,000	341,000
Calculated value of primary refined lead 2/	thousand	$337,000	$328,000

W Withheld to avoid disclosing company proprietary data; included with "Domestic ores and base bullion."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Value based on average quoted price.

TABLE 5
LEAD RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES,
BY KIND OF SCRAP AND FORM OF RECOVERY 1/

(Metric tons, unless otherwise specified)

		1999	2000
Kind of scrap:			
New scrap:			
Lead-base		42,700	35,500
Copper-base		10,100	11,400
Total		52,800	46,900
Old scrap:			
Battery-lead		1,020,000	1,020,000
All other lead-base		37,100	59,300
Copper-base		7,210	4,730
Total		1,060,000	1,080,000
Grand total		1,110,000	1,130,000
Form of recovery:			
As soft lead		635,000	651,000
In antimonial lead		444,000	428,000
In other lead alloys		18,100	36,800
In copper-base alloys		17,300	16,100
Total		1,110,000	1,130,000
Value 2/	thousands	$1,070,000	$1,090,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Value based on average quoted price of common lead.

LIME

By M. Michael Miller

Domestic survey data and tables were prepared by Lisa D. Miller, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Lime is an important chemical with numerous chemical, industrial, and environmental uses in the United States. Some evidence of its use as a lime mortar has been found at a site in what is now eastern Turkey dating between 7,000 and 14,000 years ago. More definite evidence of its use in mortars in the Near East and in the former Yugoslavia dates from 8,000 years ago. In Tibet, it was used to stabilize clays in the construction of the pyramids of Shersi 5,000 years ago. The ancient Egyptians used lime as an ingredient in mortar and plaster. The Chinese, Greek, Roman, and other ancient civilizations used lime for construction, agriculture, bleaching, and tanning (Oates, 1998, p. 3-4). Its uses began expanding with the advent of the industrial revolution, but it remained primarily a construction commodity until the rapid growth of the chemical process industries at the beginning of the 20th century. At the turn of the 20th century, more than 80% of the lime consumed in the United States was used in construction, but currently more than 90% is used in chemical and industrial applications.

The term "lime" as used throughout this chapter refers primarily to six chemicals produced by the calcination of high-purity calcitic or dolomitic limestone followed by hydration where necessary. There are two high-calcium forms—high-calcium quicklime (calcium oxide, CaO) and high-calcium hydrated lime [calcium hydroxide, $Ca(OH)_2$]. There are four dolomitic forms—dolomitic quicklime ($CaO \cdot MgO$), dolomitic hydrate type N [$Ca(OH)_2 \cdot MgO$] and dolomitic hydrate type S [$Ca(OH)_2 \cdot Mg(OH)_2$], and refractory dead-burned dolomite. Lime also can be produced from a variety of calcareous materials, such as aragonite, chalk, coral, marble, and shell. It also is regenerated (produced as a byproduct) by paper mills, carbide plants, and water-treatment plants. Regenerated lime, however, is beyond the scope of this report.

Production

Lime is a basic chemical that was produced as quicklime at 101 plants in 33 States and Puerto Rico (table 2). Hydrated lime was produced at 12 separate hydrating facilities (including 1 plant where the kiln has been shut down but hydrate was manufactured from quicklime produced offsite). In four States with no quicklime production, hydrating plants used quicklime shipped in from other States. There were also a small number of slurry plants, where lime was converted to liquid form prior to sale. Principal producing States were, in descending order of production, Missouri, Kentucky, Alabama, Ohio, Texas, and Pennsylvania.

Domestic production data for lime are derived by the U.S. Geological Survey (USGS) from a voluntary survey of U.S. operations. The survey is sent to primary producers of quicklime and hydrate but not to independent hydrators that purchase quicklime for hydration so as to avoid double counting. Quantity data are collected for 28 specific and general end uses, and value data are collected by type of lime, such as high calcium or dolomitic. Because value data are not collected by end use, value data shown in table 4 are determined by calculating the average value per metric ton of quicklime sold or used for each respondent and then multiplying it by the quantity of quicklime that the respondent reported sold or used for each end use. The table lists the total quantity sold or used for an end use and the total value of the quicklime and hydrate sold or used for that end use calculated as described above. The same methodology is used to calculate the value of hydrate sold and used in table 5.

The USGS maintains a list of operations classified as producing or idle; in 2000, there were 112 operations listed. One of these operations is not surveyed at the producer's

Lime in the 20th Century

In 1900, U.S. lime production was about 1.8 million metric tons. Historically, lime has always been a very versatile chemical, but when the first survey of lime usage was performed in 1906, nearly 83% of lime was used in building trades for mortar, plaster, and sand-lime brick. The remaining was used in agriculture (9%) and for various chemical and industrial uses (8%). Pennsylvania and Ohio accounted for more than 30% of production. There were more than 1,000 lime burners operating nationwide at the time, and most used vertical shaft kilns producing a few hundred to a few thousand tons per year. The largest lime plants only produced about 20,000 tons per year.

In 2000, the United States produced nearly 19.6 million metric tons of lime. Changes in technologies, new environmental laws, and entirely new uses have resulted in great changes in how lime is consumed. More than 83% of lime was used in descending order, for steelmaking, flue gas desulfurization, water treatment (acid mine drainage, drinking water, and waste water), nonferrous metallurgy, soil stabilization, precipitated calcium carbonate production, sugar refining, and pulp and paper manufacturing. Only about 2% of lime was consumed in traditional building trades. The two leading producing States were Missouri and Kentucky, which accounted for 21% of production. The basic lime manufacturing process had not changed; it still involved heating limestone to dissociate calcium oxide and carbon dioxide. In the past 100 years, kilns have become much larger and use computer monitoring and control systems to operate at high efficiencies. In 2000, more than 10 times as much lime was produced as in 1900, but it was produced at only 107 plants, some of which had production capacities of more than 1 million tons per year.

Digitized by Google

request, and estimates are made by using reported prior-year production figures or other industry data. Five of the listed operations were idle in 2000. Of the 108 operations to which the 2000 annual survey request was sent, 107 were in operation all or part of the year and 96 responded to the survey, representing 98% of the total sold or used by producers. Production data for the 12 nonrespondents were estimated based on prior-year production figures and other commodity data.

Total lime sold or used by domestic producers in 2000 decreased by about 100,000 metric tons (t) (110,000 short tons) to 19.6 million metric tons (Mt) (21.6 million short tons) from the revised 1999 total of 19.7 Mt (21.7 million short tons) (table 1). Production included the commercial sale or captive consumption of quicklime, hydrated lime, and dead-burned refractory dolomite. These products were valued at $1.19 billion. Commercial sales increased by 165,000 t (182,000 short tons) to 17.5 Mt (19.3 million short tons), while captive consumption decreased by 282,000 t (311,000 short tons) to 2.04 Mt (2.25 million short tons).

The most significant factor affecting the lime industry in 2000 was the impact of high natural gas prices on lime kiln operations. Because of the large increase in natural gas prices, some of the kilns burning these fuels were shut down. Fuel price increases affected mainly plants with vertical shaft and Calcimatic kilns. The commercial lime industry operates a relatively small number of these kilns, but production costs at those plants that do would have risen dramatically. Commercial plants or individual kilns in Missouri, Pennsylvania, South Carolina, Tennessee, Texas, and Virginia were shut down. Kilns in Arizona and Ohio also may have been affected. Since the peak demand season for natural gas is the winter, gas prices were expected to decrease in the spring of 2001, although industry experts still expected prices to be significantly higher than the average price in 1998 and 1999.

The largest commercial lime company in North America, Carmeuse North America, underwent an internal reorganization into central, northern, and southern regions. Plants in Illinois, Indiana, Kentucky, and Pennsylvania were allocated to the central region, plants in eastern Canada, Michigan, and Ohio to the northern region, and plants in Alabama, Louisiana, and Texas to the southern region (William S. Brown, Executive Vice President Marketing and Development, Carmeuse North America, written commun., January 19, 2001).

Graymont Ltd., the Canadian parent company of Continental Lime Inc. and others, reorganized and renamed its lime subsidiaries into the following: Graymont Western US Inc., Graymont Western Canada Inc., Graymont Dolime (OH) Inc., Graymont (PA) Inc., Graymont (QC) Inc., and Graymont (NB) Inc. Graymont produces lime in six U.S. States and five Canadian Provinces (Graymont Ltd., 2000, Related companies, accessed July 11, 2000, at URL http://www.graymont.com/related.htm).

United States Lime & Minerals, Inc. (U.S. Lime & Minerals) started up its new preheater rotary kiln on October 22 at its Arkansas Lime Co. subsidiary in Batesville, AR. The new kiln successfully achieved design volumes in excess of 540 metric tons per day (t/d) (600 short tons per day). U.S. Lime & Minerals is proceeding with financing plans for the construction of phase II of the Arkansas Lime project. The requisite permits for the installation of the phase II kiln have already been obtained, and the company expected to commence construction of phase II in midyear 2001, subject to market demand, the ability to secure competitive bids, and the availability of financing (United States Lime & Minerals, Inc., October 21, 2000, United States Lime & Minerals, Inc. announces results for the third quarter 2000, the start-up of its new kiln in Arkansas, and proposed financings, accessed April 19, 2001, via URL http://www.uslm.com/news.htm).

Chemical Lime Co. and Martin Marietta Materials, Inc., signed an agreement whereby Martin Marietta would process aggregate materials and provide certain operating services at Chemical Lime's lime plant in New Braunfels, TX. Under the agreement, Martin Marietta will build an aggregates plant to process what is currently unusable limestone for the lime plant. The plant is expected to be operational the second half of 2001 and will have an initial capacity of about 1.3 to 1.8 million metric tons per year (1.5 to 2.0 million short tons per year). Martin Marietta will also assume responsibility for all pit operations, including supplying kiln feed to the lime plant (Martin Marietta Materials, Inc., July 17, 2000, Martin Marietta Materials, Inc. announces agreement with Chemical Lime Co. in Texas, accessed September 25, 2000, at URL http://www.martinmarietta.com/corpsite/news/press_releases/00_07_17.asp). Chemical Lime's Ten Mile plant located near Bancroft, ID, shut down in late 1999 and was idle all of 2000. The facility was used as a terminal in 2000 for sales of lime produced at other Chemical Lime plants in the region.

Baker Refractories and Wülfrath Refractories GmbH, the refractories arm of the Lhoist Group of Belgium, signed an agreement to merge pending approval by antitrust authorities in Europe and the United States. The new unit will operate under a unifying name and will be headquartered in Hilden, Germany. Baker Refractories manufactures dead-burned refractory-dolomite products in York, PA, and also has manufacturing facilities in the United Kingdom and joint-venture operations in Mexico and Taiwan (Industrial Minerals, 2000).

In the captive lime sector, three plants closed permanently. The Dow Chemical Co.'s lime plant at Ludington, MI, closed in late 1999, when Dow switched to purchasing lime on the open market. Holly Sugar Co.'s sugar beet plants and their respective lime kilns located at Tracy and Woodlands, CA, closed in late 2000.

Of the 43 companies manufacturing quicklime at the end of 2000, 26 were primarily commercial producers, 13 were predominantly captive producers, and 4 combined commercial sales with captive production. During 2000, the 26 commercial producers operated 63 lime plants producing quicklime and 7 separate hydrating plants (including 1 lime plant that was idle but operated its hydrator). The 13 captive producers operated 34 plants producing quicklime primarily for internal company use. At yearend, the top 10 companies were, in descending order of production, (1) Carmeuse North America, (2) Chemical Lime, (3) Graymont Ltd., (4) Mississippi Lime Co., (5) Global Stone Corp., (6) Martin Marietta Magnesia Specialties, Inc., (7) U.S. Lime & Minerals, (8) Vulcan Materials Co., (9) LTV Steel Co., Inc., and (10) Austin White Lime Co. These companies operated 45 lime plants and 6 separate hydrating plants and accounted for 86% of the combined commercial sales of quicklime and hydrated lime and 79% of total lime production.

Domestic lime plant capacity is based on 365 days minus the average number of days for maintenance multiplied by the average 24-hour capacity of quicklime production, including quicklime converted to hydrated lime. In 2000, based on capacity data from 48 commercial plants, the U.S. lime industry

Digitized by Google

operated at about 79% of capacity compared with 76% in 1999. The calculations do not include combined commercial and captive producers, hydrating plants, and Puerto Rico.

Environment

The most common fuel used to produce lime in the United States is coal. Emissions generated in the combustion of coal and other fuels make the lime industry subject to regulation under the Clean Air Act. Of immediate concern to the lime industry are the costs and obligations expected for additional monitoring, reporting, and control of particulate matter and hazardous air pollutants such as hydrogen chloride. Of longterm concern, with a potentially greater impact, is the international debate on the reduction of greenhouse gas emissions, particularly carbon dioxide. Lime production generates carbon dioxide from the combustion of fuels and from the calcination process, which dissociates calcium carbonate into calcium oxide and carbon dioxide. Any program to regulate carbon dioxide emissions would affect lime producers.

Consumption

The breakdown of consumption by major end uses (table 4) was as follows: 38% for metallurgical uses, 26% for environmental uses, 24% for chemical and industrial uses, 11% for construction uses, and 1% for refractory dolomite. Captive lime accounted for about 10% of consumption and was used mainly in the production of steel in basic oxygen furnaces, sugar refining, and magnesia and magnesium production. Almost all data on captive lime consumption, excluding the sugar industry, are withheld to protect company proprietary information. As a result, table 4 lists the total quantity and value of lime by end use. End uses with captive consumption are listed in footnote 4 of the table. Values assigned to specific end uses in table 4 should not be construed as being price specific to that market. The USGS does not collect value data by end use, and the values shown in tables 4 and 5 are derived, in general, from average lime values. The market values shown are simply designed to show the relative value of the market.

In steel refining, quicklime is used as a flux to remove such impurities as phosphorus, silica, and sulfur. Dolomitic lime is often substituted for a fraction of the high-calcium lime to extend refractory life. Dolomitic quicklime is also used as a flux in the manufacture of glass. The steel industry accounted for about 31% of all lime consumed in the United States. Lime consumption by the iron and steel industry was 6.15 Mt (6.78 million short tons), a 2.9% increase compared with that of 1999. This increase is in part explained by the lower usage rate of lime in electric arc furnaces. The trend toward using magnesia to replace some dolomitic lime in the steel furnace appears to have leveled off after making inroads into dolomitic lime sales.

The U.S. steel industry reported strong production during the first and second quarters of 2000, but a slowing economy and increased imports resulted in a decrease in production of more than 10% in the third and fourth quarters. For the year, raw steel production was up by 4.2% (3.1%, basic oxygen process and 5.5%, electric arc process) compared with that in 1999.

In nonferrous metallurgy, lime is used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and to maintain the proper pH in the flotation process. Lime is used to process alumina and magnesia, to extract uranium from gold slimes, to recover nickel by precipitation, and to control the pH of the sodium cyanide solution used to leach gold and silver from the ore. Such leaching processes are called dump leaching when large pieces of ore are involved, heap leaching when small pieces of ore are involved, and carbon-in-pulp cyanidation when the ore is leached in agitated tanks. Dump and heap leaching involve crushing the ore, mixing it with lime for pH control and agglomeration, and stacking the ore in heaps for treatment with cyanide solution. Lime is used to maintain the pH of the cyanide solution at a level between 10 and 11 to maximize the recovery of precious metals and to prevent the creation of hydrogen cyanide. Lime consumed for these various uses is included in table 4 under the category "Other nonferrous metallurgy."

Lime usage in nonferrous metallurgy (mainly concentration of copper and gold ores, aluminum and bauxite processing, and magnesium production) decreased by 17% in 2000. Previously announced cutbacks and closures by copper producers (including the Continental Mine in Montana) were made more acute by power disruptions and high energy costs. Decreases in copper output and magnesium production were primary causes of the decrease in lime consumption. Recoverable mine production of copper decreased by about 8% (Edelstein, 2001). Magnesium production decreased by 23%; the power and energy problems of the Pacific northwest caused production problems for magnesium producer Northwest Alloys, Inc., and for its aluminum customers (Kramer, 2001).

The tailings that result from the recovery of precious metals may contain elevated levels of cyanides. Lime is used to recover cyanides in such treatment processes as Cyanisorb, alkaline chlorination, and sulfur dioxide/air.

In the environmental sector, lime is used in the softening and clarification of municipal potable water and to neutralize acid-mine and industrial discharges. In sewage treatment, lime's traditional role is to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. Lime also aids clarification and in destroying harmful bacteria. More recently, the largest use in sewage treatment has been to stabilize the resulting sewage sludges. Sewage sludge stabilization, also called biosolids stabilization, reduces odors, pathogens, and putrescibility of the solids. Lime stabilization involves mixing quicklime with the sludge to raise the temperature and pH of the sludge to minimum levels for a specified period of time. Lime consumption for all sludge treatment increased by 29% compared with that in 1999. The sewage sludge market increased by 53%, but the industrial and hazardous waste market decreased by 8%.

In flue gas desulfurization (FGD) systems serving electric utility and industrial plants and incinerators, lime is used to react with sulfur oxides in the flue gas and is used to stabilize the resulting sludge before disposal. In 2000, the FGD market grew by 13%, recouping the 10% decrease in sales reported in 1999. The utility industry increased operating and maintenance budgets, which improved plant reliability and helped eliminate much of the unscheduled downtime experienced by some powerplants in 1999. Probably just as important, after mild temperatures in 1999, temperatures returned to more normal ranges, thus increasing the demand for electricity. In addition, the price of nitrogen oxide (NO_x) emission allowances dropped. One of the large midwestern powerplants was forced to reduce

Digitized by Google

its power generation to limit NO_x emissions in 1999 but resumed normal operations in 2000.

Lime is used by the pulp and paper industry in the basic Kraft pulping process where wood chips and an aqueous solution (called liquor) of sodium hydroxide and sodium sulfide are heated in a digester. The cooked wood chips (pulp) are discharged under pressure along with the spent liquor. The pulp is screened, washed, and sent directly to the paper machine or for bleaching. Lime is sometimes used to produce calcium hypochlorite bleach for bleaching the paper pulp. The spent liquor is processed through a recovery furnace where dissolved organics are burned to recover waste heat and sodium sulfide and sodium carbonate are recovered. The recovered sodium sulfide and sodium carbonate are diluted with water and then treated with slaked lime to recausticize the sodium carbonate into sodium hydroxide (caustic soda) for reuse. The byproduct calcium carbonate is recalcined in a lime kiln to recover lime for reuse. The paper industry also uses lime as a coagulant aid in the clarification of plant process water.

The pulp and paper market was adversely affected by the slowdown of the economy and by the trend toward increased recycling of byproduct calcium carbonate into lime by pulp and paper producers. These factors resulted in a 17% decrease in lime consumption.

Lime is used to make precipitated calcium carbonate (PCC), a specialty filler used in premium-quality coated and uncoated papers, paint, and plastics. The most common PCC production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime, a suspension of hydrated lime in water, to form a precipitate of calcium carbonate and water. The reaction conditions determine the size and shape of the resulting PCC crystals. Lime use for PCC production was unchanged compared with that of 1999.

Lime is used, generally in conjunction with soda ash, for softening plant process water. This precipitation process removes bivalent soluble calcium and magnesium cations (and, to a lesser extent, ferrous iron, manganese, strontium, and zinc), which contribute to the hardness of water. This process also reduces carbonate alkalinity and dissolved solids content.

The chemical industry uses lime in the manufacture of alkalies. Quicklime is combined with coke to produce calcium carbide, which is used to make acetylene and calcium cyanide. Lime is used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk-of-lime is used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself is then removed by reaction with carbon dioxide to precipitate calcium carbonate. The carbon dioxide is obtained as a byproduct of lime production.

In construction, hydrated lime and quicklime are used in subgrade stabilization to stabilize fine-grained soils in place of materials that are employed as subbases, such as hydraulic clay fills or otherwise poor-quality clay and silty materials obtained from cuts or borrow pits. Lime also is used in base stabilization, which includes upgrading the strength and consistency properties of aggregates that may be judged unusable or marginal without stabilization. Common applications for lime stabilization included the construction of roads, airfields, building foundations, earthen dams, and parking areas. Highway projects, airport runway expansions, and commercial projects kept the large Texas stabilization market at about the same level as in 1999, but nationwide lime sales for stabilization decreased by 7% compared with the revised 1999 figures.

Although the overall quantities of lime used for soil stabilization are believed to be accurate, the data reported in table 5 may not accurately reflect how much hydrated lime is actually used in soil stabilization. Much of the lime used in soil stabilization is consumed as slurry, which may be manufactured by the lime company at a slurry plant or by the user onsite.

In road paving, hydrated lime is used in hot mix asphalt to act as an antistripping agent. Stripping is generally defined as a loss of adhesion between the aggregate surface and the asphalt cement binder in the presence of moisture. Lime also is used in cold in-place recycling for the rehabilitation of distressed asphalt pavements. Existing asphalt pavement is pulverized by using a milling machine, and a hot lime slurry is added along with asphalt emulsion. The cold recycled mix is placed and compacted by using conventional paving equipment, which produces a smooth base course for the new asphalt surface. In 2000, sales of lime for use in asphalt decreased by nearly 7% compared with the revised 1999 figures.

In the traditional building sector, quicklime is used to make calcium silicate building products, such as sand-lime brick and autoclaved aerated concrete (AAC). AAC offers the advantage of producing building materials that can be cut, drilled, and nailed like wood but with the advantages of a concrete product.

Hydrated lime is used in the traditional building sector where it still is used in plaster, stucco, and mortars to improve durability. The recent growth in this traditional lime market is the result of strong growth in nonresidential building construction (industrial buildings, offices, shopping centers, etc.) where architects have specified the use of the traditional lime building materials. According to preliminary data released by the U.S. Census Bureau, there was a 6.8% increase in the value of nonresidential building construction in 2000; the use of hydrated lime in traditional building uses increased by more than 4%. The use of hydrated lime in traditional building uses has increased by 33% since 1997.

A small amount of hydrated lime (estimated to be less than 2% of total building uses) also is used on the renovation of old structures built with lime-based mortars, which were standard before the development of portland cement-based mortars. Modern portland cement-based mortars are incompatible with old lime mortars.

Dead-burned dolomite, also called refractory lime, is used as a component in tar-bonded refractory brick used in basic oxygen furnaces. Hydrated lime is used to produce silica refractory brick used to line industrial furnaces.

Prices

The average values per ton of lime, rounded to three significant figures, are listed in table 8. The values are reported in dollars per metric ton with accompanying conversions into dollars per short ton. For accuracy, the conversions were made from the unrounded metric value and, as a result, may not be an exact conversion of the rounded values. All value data for lime are reported by type of lime produced—high-calcium quicklime, high-calcium hydrate, dolomitic quicklime, dolomitic hydrate, and dead-burned dolomite. Emphasis is placed on the average value per ton of lime sold.

In 2000, the average value for all types of lime sold and used was essentially unchanged from the previous year. Although

Digitized by Google

there was some upward movement in commercial lime prices on an free on board plant basis (less than 2%), because much of the quicklime is sold through long-term contracts to such large customers as steel mills and utilities, significant price increases cannot be enacted until current contracts expire. In some cases, however, lime companies passed along increased fuel and energy costs in the form of surcharges.

The average value per ton of high-calcium quicklime and high-calcium hydrate sold increased only slightly, but dolomitic quicklime and dolomitic hydrate values per ton of lime sold increased by 7% and 17%, respectively. The increase in price for dolomitic quicklime was partly the result of an increase in the steel producer price index in 2000. Steelmaking is the largest market for dolomitic quicklime, and lime supply contracts are sometimes tied to the steel index. In addition, there is increased use of dolomitic quicklime in higher value specialty products manufactured for the steel markets.

Overall, despite idled capacity, strong competition continued to keep prices down. Figures 1 and 2 show the average sales value per ton of quicklime and hydrate over the past 10 years in actual and constant dollars.

Foreign Trade

The United States exported and imported quicklime, hydrated lime (slaked lime), hydraulic lime, and calcined dolomite (dolomitic lime). Combined exports of lime (table 6) were 73,200 t (80,700 short tons) valued at $9.96 million, with 69% exported to Canada, 17% exported to Mexico, 9% exported to Argentina, and the remaining 5% going to various other countries. Combined imports of lime (table 7) were 113,000 t (125,000 short tons) value at $13.5 million, with 85% coming from Canada and 14% coming from Mexico.

Data on imports and exports of hydraulic lime may be questionable. There is only one known producer of hydraulic lime in the United States, and with exports averaging about 10,000 to 11,000 metric tons per year (t/yr) in 1999 and 2000, it is likely that what is being classified as hydraulic lime is in fact portland cement (or some other hydraulic cement product). Chemically, hydraulic lime and portland cement are quite similar.

No tariffs are placed on imports of hydraulic lime, quicklime, and slaked lime from countries with normal trade relations (NTR) with the United States. There is a 3% ad valorem tariff on imports of calcined dolomite from NTR countries.

World Review

With the exception of industrialized nations with good data collection, accurate lime data for many countries are frequently difficult to acquire. The variations in quality, types of lime, production technologies, and industries manufacturing lime and the frequent confusion with limestone data make accurate reporting of world lime data (table 9) extremely difficult and certainly incomplete. The following is a brief discussion of acquisitions or new construction in specific countries.

Italy.—Calcestruzzi Calò A has purchased a 200-t/d Cim-Reversy oil-fired kiln from Cimprogetti S.p.A. (World Cement, 2001).

Jamaica.—Rugby Jamaica Lime and Minerals Ltd. successfully commissioned its new 400-t/d lime plant near Clarendon. The plant includes a Cimprogetti Twin-D 85 twin shaft regenerative kiln and will supply lime to the local alumina industry (World Cement, 2001).

Mexico.—Mexico's Grupo Calider S.A. de C.V., a joint-venture partner of the Belgian Lhoist Group, acquired Mexican lime producer Caleras Fernandez S.A. de C.V. Caleras Fernandez, which operates in southwestern Mexico, has a 300,000-t/yr plant near Guadalajara and a 35,000-t/yr hydrating plant near Cimarron (Lhoist Group, July 2000, Acquisition of Mexican Caleras Fernandez, accessed January 5, 2001, at URL http://www.lhoist.com/about/news/intro.html).

Peru.—Cia. De Minas de Buenaventura S.A. de C.V. successfully commissioned its new oil-fired Cimprogetti Cim-Reversy twin shaft regenerative kiln. The 130-t/d kiln is located at the Yanococha Gold Mine (World Cement, 2001).

Poland.—In November 2000, Lhoist Bukowa Sp. zo. o. started up its new 600-t/d Maerz kiln. The new kiln increases the plant's capacity to 1,760 t/d and makes it the most modern lime plant in the Kielce region. Additional work on a new hydrating plant and pebble lime storage facilities are expected to be completed by June 2001 (Lhoist Group, November 2000, New kiln at Lhoist Bukowa, accessed April 30, 2001, at URL http://www.lhoist.com/about/news/intro.html).

Spain.—Caleras De San Cucao has placed an order for a Cimprogetti gas-fired Twin-D 70 kiln. The kiln is designed to alternate between producing high-calcium lime and dolomitic lime (World Cement, 2001). A Maerz lime kiln was installed at Ciarues S.A.'s Aragon plant. The new kiln has a capacity of 200 t/d and is natural-gas/coal-dust fired (World Cement, 2001).

United Kingdom.—On December 14, the Lhoist Group of Belgium acquired the United Kingdom lime business of RMC Group plc. The acquisition includes two Maerz kilns with an annual capacity of 200,000 t/yr near Hindlow, Derbyshire, and a hydrating plant near Hartley, Cumbria. The new entity will operate under the name Lhoist UK Ltd. (Lhoist Group, December 2000, Lhoist purchases RMC lime in the UK, accessed January 5, 2001, at URL http://www.lhoist.com/about/news/intro.html).

Outlook

Lime has dozens of end uses in the chemical, industrial, and construction industries, but sales are dominated, in descending order by tonnage, by the iron and steel markets, FGD, pulp and paper including the related PCC market, construction, and nonferrous metallurgy. These market groups accounted for 75% of total lime consumption in 2000.

In the short term, the slowdown of the economy and the energy crisis in the western United States will have a negative impact on lime sales. The domestic steel industry is plagued by high levels of imports, large inventories, and bankruptcies; the slowing economy will only exacerbate the industry's problems. These factors are expected to cause a decrease in U.S. steel production in 2001, and lime sales for steel could be decline by 5% to 10% in 2001.

In 2000, the FGD market recovered from the problems experienced in 1999, and the future for the lime-based FGD remains promising. Phase II of the Clean Air Act Amendments (CAAA), which went into effect January 1, 2000, remains the driving force behind the growth in this market. The costs of lime-based scrubbers have decreased to about $330 per ton of sulfur dioxide removed (from $440 to $1,000 per ton), and lime scrubbers display favorable economics and efficiencies for the

Digitized by Google

smaller units regulated under phase II. Regulations covering emissions from small municipal incinerators and waste-to-energy incinerators also favor the use of lime scrubbers. When phase II went into effect, it was thought that the real boost to lime sales for FGD would be slow in coming because of an excess of emission allowances accumulated during phase I of the CAAA and the low prices for emissions allowances. It was thought that it would likely take until 2005 for the scrubber market to really start seeing the demand increase from the phase II regulation. There has been a steep rise in the price of emissions allowances from about $130 per ton to more than $200 per ton between the fall of 2000 and the spring of 2001. If allowance prices continue to rise or stay at current levels, the economics of installing scrubbers may become more attractive earlier than the previously forecasted 2005 time period.

Analysis of the energy crisis of 2000 and the potential for energy shortages in the future has indicated that the quickest way to expand generating capacity is to maximize the use of existing powerplants and to add capacity at current facilities. There continues to be strong public support for environmental cleanup of emissions, so greater use of FGD controls is likely in the future. The higher prices of natural gas, which has been the preferred fuel for new powerplants, also has made coal a more acceptable option for future power plant construction.

In a recent forecast of air pollution control markets, The McIlvaine Co. predicted that U.S. utilities will spend $25 billion over the next 9 years on flue gas desulfurization. The majority of these systems will use lime or limestone and produce byproduct gypsum. About 60% will be for existing powerplants and 40% for new coal-fired powerplants (The McIlvaine Co., November 2000, Huge U.S. power plant scrubber market now developing, accessed April 30, 2001, at URL http://www.mcilvainecompany.com/news%20releases/NR600.htm).

Increased funding for highway and airport construction as authorized by the Transportation Equity Act for the 21st Century (TEA-21) and the Wendell H. Ford Aviation Investment and Reform Act for the 21st Century (AIR-21) should benefit the soil stabilization and asphalt markets over the next several years. The following are two examples of projects that potentially could benefit from the acts. AIR-21 will help fund runway expansion projects that have been announced for Corpus Christi International Airport, Dallas-Fort Worth International Airport, and McAllen-Miller International Airport (located west of Brownsville, TX). In addition, TEA-21 designated the "Ports to Plains" corridor linking Denver, CO, with the Texas-Mexico border as 1 of 43 high-priority corridors. Several transportation studies have been conducted on this corridor in the past, but a major feasibility study is underway that will examine preferred highway alignments and the feasibility of highway improvements. The goal would be to develop a four-lane divided highway linking the two points (Wilbur Smith Associates, January 2001, Ports to plains feasibility study process, accessed May 1, 2001, at URL http://www.wilbursmith.com/portstoplains). If this corridor gets built, it would provide a large potential market for lime stabilization that could last for years.

The traditional building markets (masonry and finishing lime) have shown unexpected growth in recent years and the trend should continue, but with the economy lagging in 2001 the growth rate of nonresidential construction is likely to slow.

Sales to the traditional pulp and paper market have decreased in recent years mainly because of increased recycling of byproduct calcium carbonate. This market will also be adversely affected by the announced closure of three International Paper Co. mills at Mobile, AL, Camden, AR, and Lock Haven, PA, and reduced operations at Courtland, AL (Tappi, October 20, 2000, PACE addresses mill closures, downsizing at IP, accessed November 15, 2000, via URL http://www.tappi.org). These closures will also adversely affect the PCC market because Minerals Technologies, Inc., operates satellite PCC mills at Lock Haven and Mobile, although PCC production at Courtland will be unaffected. On the positive side, Minerals Technologies opened a new merchant PCC mill at Brookhaven, MS, which will manufacture PCC for such nonpaper uses as vinyl siding and automotive and construction sealants (North American Minerals News, 2000b). In addition, Minerals Technologies signed an agreement to construct a satellite PCC mill at a paper mill in Millinocket, ME, owned by Great Northern Paper, Inc. The plant is expected to be in operation in the third quarter of 2001 (North American Minerals News, 2001). Despite the closures by International Paper, which will slow the growth of PCC in 2001, the PCC market should exhibit solid growth in the long term. Its penetration of the groundwood paperboard markets is considered a driver of future PCC demand. Kline & Co., a consultancy based in Fairfield, NJ, expects PCC use in paper and paperboard to grow on average by 6% per year through 2004 (North American Minerals News, 2000a).

The increase in natural gas prices already has had a dramatic effect on lime plant operations. With gas prices expected to remain high and coal prices rising because of increased demand as gas users try to switch fuels, lime plant operating costs will increase. Higher prices for transportation fuels (mainly diesel) will also increase operating costs. If these fuel prices continue at elevated levels, as current long-term contracts expire, lime producers will certainly attempt to raise prices. In the long term, coal prices are expected to come down as coal mine output catches up with demand. Considering the strong competition between lime companies and excess production capacity, the biggest impact of the current energy problems on the lime industry likely will not be big price increases but rather more production from coal-fired kilns. Companies will, where possible, convert gas-fired kilns to coal firing, but it is not known if this is feasible for all types of kilns.

LITHIUM

By Joyce A. Ober

Domestic survey data and tables were prepared by Maria Arguelles, statistical assistant, and the world production tables were prepared by Regina R. Coleman, international data coordinator.

Introduction

Chile was, once again, the world's leading producer of lithium carbonate with production at its two lithium operations on the Salar de Atacama in the Andes Mountains. There was one lithium carbonate plant in Argentina on the Salar del Hombre Muerto, but it operated at a level far below its capacity. In addition, production of lithium chloride continued in Argentina. One lithium carbonate plant continued to operate in Nevada. Chinese and Russian lithium carbonate production continued; Australia, Canada, and Zimbabwe were important sources of lithium ore concentrates.

A large percentage of the material produced in South America was exported to the United States as feed material for the production of downstream lithium compounds and in industrial applications. The United States remained the world's leading producer of value-added lithium compounds and also the leading lithium consumer.

Because lithium is electrochemically reactive and has other unique properties, many commercial lithium products are available. With an estimated market value of $500 million worldwide, producers sell lithium as mineral concentrate, brine, chemical, or metal depending on the end use. Most lithium compounds and minerals are consumed in the production of ceramics, glass, and primary aluminum, although the use of organic lithium compounds as industrial catalysts and the consumption of various lithium compounds in lithium batteries are the most rapidly expanding markets.

Production

The U.S. Geological Survey collects domestic production data for lithium from a voluntary survey of U.S. operations. The single remaining lithium carbonate producer responded to the survey, representing 100% of total production. Production and stock data were withheld from publication to avoid disclosing company proprietary data (table 1).

Chemetall Foote Corp., a subsidiary of the German company Chemetall GmbH, produced lithium carbonate from brines near Silver Peak, NV. The company's other lithium operations included a lithium hydroxide plant in Silver Peak; a butyllithium plant in New Johnsonville, TN; and facilities for producing downstream lithium compounds at the site of an idle spodumene (a lithium aluminum silicate ore) deposit in Kings Mountain, NC.

FMC Corp., Lithium Division, produced a full range of downstream compounds, including lithium metal and organic lithium compounds at its facilities in Bessemer City, NC, and Bayport, TX. FMC operated a lithium carbonate plant and spodumene mine in North Carolina until 1998. Since 1999, the company has met its lithium carbonate requirements through a long-term agreement with Chilean producer Sociedad Quimica y Minera de Chile S.A. (SQM) to supply FMC with lithium carbonate produced at SQM's brine operation. FMC determined

Lithium in the 20th Century

In 1900, the lithium industry was practically nonexistent; the United States produced 470 metric tons of lithium minerals, containing less than 10 tons of lithium. Early in the century, several lithium minerals, including amblygonite, lepidolite, and spodumene, were produced in California and South Dakota and were used in specialty glass, enamels, and glazes. Some minerals were shipped overseas for conversion into lithium compounds, especially lithium hydroxide, which was used for batteries and in certain pharmaceutical applications. Domestic lithium chemical production began in 1905. The lithium industry grew significantly during World War II, when lithium compounds were used in military applications. Lithium hydride was used to generate hydrogen to inflate antenna balloons for rescue radios; anhydrous lithium hydroxide was and is still used to absorb carbon dioxide in submarines and later in manned spacecraft. After the war, the lithium industry searched for and promoted industrial uses of lithium compounds to replace markets lost. New markets were developed in the multipurpose grease industry and as welding fluxes. During that time, lithium minerals continued to be used in ceramics and glass, and newly developed pyroceramics (materials that expanded and contracted very little at extreme temperatures) were used in nosecones of spacecraft. These materials were later marketed for cookware that became very popular because of its durability. The United States was the leading producer of lithium materials for most of the 20th century, with spodumene mines in North Carolina being the dominant sources of raw materials and lithium brine operations in California and Nevada becoming other important sources. Chile overtook the United States as the world's leading producer in 1998, the year the final spodumene operation in the United States closed.

In 2000, the United States was still the leading producer of downstream lithium compounds and the leading consumer of all types of lithium materials with an estimated consumption of 2,800 tons of contained lithium. Lithium minerals continued to be important in the ceramics and glass industry. Lithium compounds were used in primary aluminum production, lubricants, lithium battery components, industrial air-conditioning and commercial dehumidification systems, production of sophisticated textiles, sanitizers for swimming pools and public restrooms, and dry bleaches for commercial laundries.

Digitized by Google

that the supply agreement with SQM would be more economical than continuing to produce lithium carbonate from its own operation in Argentina that was completed in 1997 (FMC Corp., 2001). FMC produced lithium chloride and minor quantities of lithium carbonate in Argentina in 2000.

LithChem International, a subsidiary of ToxCo, Inc., both of Anaheim, CA, produced lithium carbonate and lithium hydroxide at its facilities in Baltimore, OH. LithChem produces these compounds from lithium compounds that are products of ToxCo's lithium battery recycling operation in Trail, British Columbia, Canada. In 2000, LithChem acquired Ozark-Mahoning Co.'s inorganic fluorine compounds facility in Tulsa, OK, from Atofina Chemicals Inc. and renamed it Ozark Fluorine Specialties Inc. LithChem plans to use some of the hydrofluoric acid produced at Ozark's facility to make lithium hexafluorophosphate, high-purity lithium fluoride, and other electrolytes used in lithium batteries. The lithium electrolyte compounds used in lithium ion batteries currently (2000) are produced commercially by only one company in Japan (Hunter, 2000).

Lithium carbonate is the most important lithium compound produced from brine and ore deposits. In most cases, other lithium compounds require lithium carbonate as a feedstock for further processing. Domestic production of lithium carbonate from brine is limited to Chemetall Foote's operation in Nevada. Nevada brines enriched in lithium chloride, which averaged about 300 parts per million (ppm) when operations began in 1966 (Engineering and Mining Journal, 1970), are pumped from the ground and progress through a series of evaporation ponds. Over the course of 12 to 18 months, concentration of the brine increases to 6,000 ppm lithium through solar evaporation. When the lithium chloride reaches optimum concentration, the liquid is pumped to a recovery plant and treated with soda ash, precipitating lithium carbonate. The carbonate is then removed through filtration, dried, and shipped. A similar process is used to recover lithium from the Chilean brines, with slight adjustments to account for their different chemistries. The brine operation in Argentina uses a different, proprietary technology that allows for the lithium recovery as either carbonate or chloride (FMC Corp., 1998).

Until the last domestic mine closed in 1998, spodumene was the major raw material required for the production of lithium carbonate in North Carolina, and small amounts of spodumene concentrate were produced for sale. Spodumene is the most common lithium ore, but petalite and lepidolite are other types that are mined in different parts of the world. These three are beneficiated to produce lithium ore concentrates that can be used directly in certain applications.

Extracting lithium from spodumene entails an energy-intensive chemical recovery process, which is more costly than that used for brines. Because of the high cost of producing lithium carbonate from spodumene, most lithium carbonate production has shifted to the brine deposits. After mining, spodumene is crushed and undergoes a flotation beneficiation process to produce concentrate. The concentrate is heated to 1,075° C to 1,100° C, changing the crystal structure of the mineral and making it more reactive to sulfuric acid. A mixture of finely ground converted spodumene and sulfuric acid is heated to 250° C, forming lithium sulfate. Water is added to the mixture to dissolve the lithium sulfate. Insoluble portions are then removed by filtration. The purified lithium sulfate solution is treated with soda ash, forming insoluble lithium carbonate that precipitates from solution. The carbonate is separated and dried for sale or use by the producer as feedstock in the production of other lithium compounds.

Consumption

The aluminum, ceramics and glass, lubricating grease, and synthetic rubber industries used most of the lithium minerals and compounds sold in 2000. Estimated domestic consumption has been stable since 1997. Ceramics and glass production and aluminum smelters were the largest consumers of lithium carbonate and lithium concentrates worldwide, representing an estimated 50% of the total lithium market. Other consuming industries were lubricants, 18%; batteries, 9%; catalysts for synthetic rubber and pharmaceuticals, 9%; and other uses, 14% (Schmitt, 2000). Domestic end uses differ from global consumption and are described below.

The largest use of lithium in the United States was in ceramics and glass manufacturing processes. These additions, which can be made as lithium carbonate or ore concentrates, lower process melting points, reduce the coefficient of thermal expansion and the viscosity, and eliminate the use of more toxic compounds. Lithium ore concentrates were consumed exclusively in the production of ceramics and glass products. The domestic manufacture of thermal shock-resistant cookware (pyroceramics) consumed the majority of lithium used in the ceramics and glass industry. The manufacture of black-and-white television picture tubes consumed significant amounts of lithium concentrates overseas. Low-iron spodumene and petalite were sources of the lithium used to improve the physical properties of container and bottle glass, and sources of alumina, another important component of the glass. Glass manufacturers used lithium in container and bottle glass, enabling them to produce lighter weight, thinner walled products. Until 1997, lithium ore concentrates were the only lithium products that were acceptable for most ceramics and glass applications because of their low cost in comparison to lithium carbonate. Applications sensitive to other elements and impurities that came with ore concentrates and the price of lithium carbonate were not able to take advantage of the benefits of lithium in their production processes. When the lithium carbonate price was cut to about one-half of its previous level, these specialty glass producers were economically able to change their glass formulations to take advantage of the improved properties made possible by lithium additions (Sheets and Rios, 1999).

The second largest use is in primary aluminum production, especially at older smelters. Adding lithium carbonate to aluminum potlines lowers the melting point of the bath, allows a lower operating temperature for the potline, increases the electrical conductivity, and decreases viscosity of the bath. These factors contribute to increased production or reduced power consumption. Perhaps more important are the environmental benefits of lithium addition to aluminum potlines—reducing fluorine emissions by 20% to 30% (Chemetall GmbH, 2001, Lithium applications, accessed April 2, 2001at URL http://www.chemetalllithiumcom/lithium/lithium.nsf/Frame/25083639DDB37807C125693D00491D90).

Domestically, the third largest and the fastest growing end use for lithium compounds was as catalysts in the production of synthetic rubbers, plastics, and pharmaceuticals. N-butyllithium initiated the reactions between styrene and butadiene that form abrasion-resistant synthetic rubbers that require no

vulcanization. Other organic lithium compounds were catalysts for the production of plastics, such as polyethylene. Lithium metal and compounds were catalysts in the production of an analgesic, anticholesterol agents, antihistamines, contraceptives, sleep inducers, some steroids, tranquilizers, vitamin A, and other products. Pharmaceutical-grade lithium carbonate was used in the treatment of manic-depressive psychosis. This was the only treatment approved by the U.S. Food and Drug Administration in which lithium was consumed by the patient.

The multipurpose grease industry was another of the important markets for lithium in 2000. Lithium hydroxide monohydrate was the compound used for the production of lithium lubricants. Lithium-based greases were favored for their retention of lubricating properties over a wide temperature range; good resistance to water, oxidation, and hardening; and formation of a stable grease on cooling after melting. These greases continued to be used in military, industrial, automotive, aircraft, and marine applications.

The use of lithium in batteries and the belief that lithium batteries may be the best way to power electric vehicles (EVs) have spurred tremendous interest in lithium and lithium deposits to provide resources for the anticipated increased demand. Almost all major battery manufacturers marketed some type of lithium battery, and research and development continued. New battery configurations continued to be developed and continued interest in EVs drove additional interest in battery research. New, more efficient types of rechargeable (secondary) lithium batteries have been developed and older designs improved to meet the requirements of the EV market and of electronic equipment, such as portable telephones, portable computers, and video cameras. Research continued on lithium-ion batteries. These batteries were of particular interest because they take advantage of the large power capacity available from lithium batteries with fewer safety problems than are encountered when batteries contain lithium metal, a very reactive and volatile material when exposed to air and moisture. Nissan Motor Corp. U.S.A. introduced its first EV available in the United States at the 1998 Los Angeles Auto Show. The four-passenger minivan was powered by lithium-ion batteries developed jointly by Nissan and Sony Corp. This was the first EV from any automobile company that used lithium-ion batteries (Advanced Battery Technology, 1998).

Nonrechargeable (primary) lithium batteries offer improved performance over alkaline batteries at a slightly higher cost and have been commercially available for more than 10 years. They are used in watches, microcomputers, cameras, small appliances, electronic games, and toys. The military purchased large and small lithium batteries for a variety of military applications. In 2000, two lithium oxyhalide reserve batteries were qualified for use in different missile programs, the High Altitude Area Defense and the Boeing Ground Based programs. Reserve batteries provide high current for short times from small packages (McHale, 2000).

Aircraft manufacturers in several countries have considered using aluminum-lithium alloys for wing and fuselage skin or structural members in different types of aircraft. Use of these alloys could reduce the weight of the aircraft by more than 10%, allowing significant fuel savings during the life of the aircraft. The alloys, which are 2% to 3% lithium by weight, were attractive to the aircraft and aerospace industries because of their reduced density and superior corrosion resistance compared with conventional aluminum alloys. These alloys, however, have not been as widely used in aircraft manufacture as was hoped at the initial introduction of the alloys. In airplane construction, these alloys faced direct competition from composite materials consisting of boron, graphite, or aramid fibers imbedded in polymers. McCook Metals LLC produced an aluminum-lithium alloy that is being used for a fatigue-critical aft bulkhead replacement and other parts on the F-16 fighter plane built by Lockheed Martin Corp. The alloy was produced at the McCook, IL, plant formerly owned by Reynolds Metals Co. (Light Metal Age, 1998).

The National Aeronautics and Space Administration selected a new design by Lockheed Martin Manned Space Systems for the external space shuttle fuel tank; this is the only part that is not reused. The superlightweight tank was made with another aluminum-lithium alloy containing 4% copper, 1% lithium, 0.4% silver, 0.4% magnesium, and the remainder aluminum. This alloy was 30% stronger and 5% less dense than the aluminum alloy previously used. The redesigned fuel tank weighed about 3,400 kilograms less than the original design; the weight savings were used to increase the payload capacity for shuttle missions. Reynolds Metals and McCook Metals were to produce 25 of the redesigned fuel tanks (Light Metal Age, 1998).

Small quantities of other lithium compounds were important to many industries. Lithium chloride and lithium bromide were used in industrial air-conditioning and commercial dehumidification systems and in the production of sophisticated textiles. Sanitizers for swimming pools, commercial glassware, and public restrooms contained lithium hypochlorite, as did dry bleaches for commercial laundries. Lithium metal was used as a scavenger to remove impurities from copper and bronze, and anhydrous lithium chloride was used as a component in fluxes for hard-to-weld metals, such as steel alloys and aluminum.

Prices

Although yearend 2000 published prices for lithium carbonate were the same as those listed in trade publications in 1999, actual prices paid by customers were believed to be significantly lower than those published. The vigorous entrance into the market of SQM in 1998 prompted Chemetall Foote and FMC to reduce their prices comparably, although actual price lists and quotations have been difficult to obtain since the price reductions began. SQM entered the market offering lithium carbonate at about $2.00 per kilogram ($0.90 per pound); effective October 1, 1999, the company raised its price by about 10% to around $2.20 per kilogram ($1.00 per pound) (Industrial Minerals, 1999b). Chemetall and FMC announced price increases of 8% and $0.22 per kilogram ($0.10 per pound), respectively, at the end of 2000, although no specific prices were published (Industrial Minerals, 2000b).

Customs values for lithium carbonate entering the United States from Chile are a good indication of the trends in lithium pricing, although they have never reflected exactly the producers' average prices for lithium carbonate. The average unit value calculated from the U.S. Census Bureau data using Customs value and quantity imported, showed that the unit value of lithium carbonate decreased 46% from 1996 to 1999; the average value increased almost 7% in 2000. The unit value for lithium carbonate from Chile has decreased steadily from $2.70 per kilogram in 1996 to $1.45 in 2000. Imports from Argentina were recorded for the first time in 1998; the unit value for this

Digitized by Google

material in 2000 was $3.06 per kilogram. Even the highest values listed here were significantly lower than the published price of $4.47 per kilogram (table 2).

Foreign Trade

Total exports of lithium compounds from the United States decreased significantly in 1998 as compared with the previous years; exports have continued at the lower level. Because of the closures of the spodumene mine and lithium carbonate plant in North Carolina, lithium carbonate production in the United States has decreased substantially. The reduced production made lower exports inevitable. Commitments to overseas customers were supplied from operations in South America. About 68% of all U.S. exports of lithium compounds were to Canada, Germany, India, Japan, and the United Kingdom (table 3).

Imports of lithium compounds increased nearly 10% in 2000. In 2000, 88% of lithium imports was from Chile; and lithium carbonate from Argentina was 7.5% of total imports (table 4). Lithium ore concentrates from Australia, Canada, and Zimbabwe were believed to have been consumed in the United States, but no import statistics were available.

World Review

A small number of countries throughout the world produced lithium ore and brine. Chile and the United States were the leading producers of lithium carbonate. Significant quantities of lithium compounds and ore concentrates also were produced in Argentina, Australia, Canada, Chile, China, Portugal, Russia, and Zimbabwe. Brazil produced smaller quantities, primarily concentrates; Namibia, Rwanda, South Africa, and Zaire are past producers of concentrates. Production figures for lithium ore concentrates and lithium carbonate are shown in table 5. Pegmatites containing lithium minerals have been identified in Austria, France, India, Ireland, Mozambique, Spain, and Sweden, but economic conditions have not favored development of the deposits. Lithium has been identified in subsurface brines in Bolivia, China, and Israel. Companies in France, Germany, Japan, Taiwan, and the United Kingdom produced downstream lithium compounds from imported lithium carbonate.

Argentina.—After only one full year of lithium carbonate production from its lithium brine operation at the Salar del Hombre Muerto in the Argentine Andes, FMC shuttered the facility in July (Brown, 1999) except for limited production for a specialized market (Saller and O'Driscoll, 2000, p. 45). The operation was designed to produce about 12,000 metric tons per year (t/yr) of lithium carbonate and about 5,500 t/yr of lithium chloride (North American Minerals News, 1998), but technical problems and poor market conditions forced FMC to reevaluate its project, choosing to close the facility and purchase most of its lithium carbonate requirements from other sources, SQM in particular. The lithium chloride production line continued to operate (Industrial Minerals, 1999a). A proprietary selective purification process developed by FMC reduced the number of steps required to recover lithium chloride from the brine and reduced the cost of production (FMC Corp., 1998).

Canada.—Tantalum Mining Corp. of Canada Ltd. (Tanco), a subsidiary of Hudson Bay Mining Co., operates a spodumene mine and concentrating plant at Bernic Lake, Manitoba. Avalon Ventures Ltd. was developing the company's Separation Rapids rare metals project in northwestern Ontario not far from the Tanco operation. Avalon was increasing the capacity of its flotation pilot plant to be able to produce large enough volumes to provide potential customers with enough high-grade petalite concentrate for sampling. The company expected to market most of its product to glass and ceramics producers in the Ohio River Valley in the United States (North American Mineral News, 2000b, p. 12).

The Tanco operation and the Avalon project are on opposite ends of a pegmatite body that extends for more than 8 kilometers (5 miles) from Manitoba into Ontario. Amzin Minerals Ltd., the offshore holding company of Bikita Minerals Ltd., the Zimbabwe petalite producer, planned to produce petalite at a site owned by Emerald Fields Resource Corp., a Canadian company, on the same pegmatite body between the Tanco and Avalon operations. This operation was named the Big Mack. A sample was evaluated and approved by Corning Inc. for its acceptability for ceramics and glass uses. Another sample was sent to Zimbabwe to determine if it was appropriate for beneficiation using Bikita technology. If all the tests turned out as expected, construction of a plant with an initial production capacity of 15,000 t/yr of petalite concentrate was to begin by the spring of 2001. Resources at the Big Mack are conservatively estimated at 300,000 metric tons; but only a small portion of Emerald Fields' 18,200 hectares (45,000 acres) have been drilled (Industrial Minerals, 2000a).

Lithium Metal Technologies Inc. (Limtech), a subsidiary of Lithos Corp., both Canadian companies, was evaluating options for expanding its high-purity lithium carbonate plant to produce more than its current 300 t/yr for sale to specialty glass manufacturers. Limtech purifies technical-grade lithium carbonate from about 99.3% purity to a high-purity 99.999% product that can sell for $50 to $70 per kilogram. The company was considering an additional production line with capacity of 1,000 t/yr (North American Mineral News, 2000a).

Raymor Industries Inc. announced the successful development of a process to produce lithium metal directly from spodumene. The process was developed and tested at McGill University's Department of Mining and Metallurgical Engineering under contract with Raymor Industries. Raymor Industries asserted that the new process would entail the lowest production costs and highest purity for lithium metal production. The company was granted exclusive rights to the new technology that was to be patented. For feed stock, Raymor Industries intended to use spodumene mined from its La Motte deposit in Quebec and purchased spodumene (Raymor Industries Inc., 2000). A drilling project at the La Motte deposit estimated reserves at 4.55 million metric tons (Mt) at 1.07% Li_2O from the surface to the depth of 100 meters (m) with an additional 2.5 Mt below 100 m. The first phase of development involved the construction of a concentration plant to process the ore from an open pit mine. Following the completion of the processing plant, Raymor Industries planned to use the new process to produce lithium metal directly from the spodumene ore without going through the steps required by more traditional lithium metal production (North American Minerals News, 1999).

Chile.—With two large brine operations at the Salar de Atacama and their associated lithium carbonate plants, Chile has become the largest lithium carbonate producer in the world. Chemetall Foote's plant first produced lithium carbonate in 1984; it uses its lithium carbonate as feedstock for its

Digitized by Google

downstream chemical production in the United States, and supplies its parent company Chemetall's operations in Germany and Taiwan. SQM completed its first full year of production in 1997 and was planning to increase capacity by 8% to 10% from the original 20,000 t/yr (Industrial Minerals, 1999c); the company was considering expanding into downstream compounds by building a butyllithium plant in Texas and facilities to produce battery materials (Schmitt, 2000). Both companies transport concentrated brines from the Salar to lithium carbonate plants in Antofagasta. Because of SQM's agreement to supply FMC's lithium carbonate requirements, the global market was divided evenly between Chemetall Foote and SQM except for smaller quantities from China and Russia (McCoy, 1999).

China.—Lithium carbonate production in China is from domestic and Australian spodumene ore. Production was limited in 1999 because of the availability of lower cost material from Chile (McCoy, 1999). No significant increase in production was expected in the near future. Tibet Lithium New Technology Development Co., formed as a joint venture by China's Geological Research Institute (20%), Tibet Mineral Development Co. (40%), and Yuxin Trading Co. (40%), was developing a lithium project at the Zabuye Salt Lake in Tibet. A 10-year study at the salt lake identified high concentrations of boron, bromine, cesium, lithium, and potassium. Lithium production within 3 years was the goal of the company (Saller and O'Driscoll, 2000, p. 47). Another lithium project at salt lakes in the Qinghai Province was being considered. Pacific Lithium Ltd., a New Zealand company, reached agreement with the Qinghai Province to create Qinghai Lithium Ltd. (QLL), a joint venture, to study and develop the salt lake resource that was discovered in 1965. QLL's lithium resources were estimated at 1 Mt lithium, more than 1 Mt boron, and more than 17 Mt potassium (Pacific Lithium Ltd., 2000, Qinghai Lithium Limited, accessed April 4, 2000, at URL http://www.pacificlithium.com/technology/associations.html).

Germany.—Chemetall GmbH, the parent company of Chemetall Foote, has been a major producer of lithium compounds for many years at its lithium operations in its Langelsheim plant. In 2000, the company expanded its capacity for the production of lithium aluminum hydride by 50%; another facility was built to produce lithium aluminum hydride solutions. Chemetall is the world's leading producer of lithium aluminum hydride, a versatile reducing agent used in the synthesis of active substances in the pharmaceutical industry. It is marketed as a powder, in tablet form, and in solution (Chemetall GmbH, 2000). Chemetall opened a butyllithium plant in Taiwan in 1999 in response to the growth in demand for organic lithium catalysts (Industrial Minerals, 1999a).

Outlook

The health of the lithium industry remains closely tied to the performance of the primary aluminum and the ceramics and glass industries and the economy in general. Changes in consumption of lithium in these industries determine the performance of the entire lithium industry. Because these uses represent such a high percentage of the total lithium market, growth in other areas has a much smaller influence, although battery and catalyst applications are becoming more important. Demand for N-butyllithium continued to increase, and producers considered more capacity increases to meet that demand. Demand for lithium metal for batteries and to some extent for alloys will probably increase, but total consumption of metal will remain low in comparison with the demand for lithium compounds.

Lithium-ion and lithium-polymer batteries appear to possess the greatest potential for growth for the entire lithium industry. First introduced in 1993 with minimal sales, the market for these rechargeable batteries grew to $3 billion in 1998 and is expected to top $6 billion by 2005 (Pacific Lithium Ltd., 2000, Applications markets, accessed April 4, 2000, at URL http://www.pacificlithium.com/profile/markets.html). No estimates of the amount of lithium required for these batteries have been made; but the value of lithium materials sold for battery production was estimated to be $111 million in 1997, with forecasts of an average annual increase of 16% through 2008 (Saller and O'Driscoll, 2000, p. 41). This kind of value growth indicates that material demand could increase at a comparable rate or quite probably more quickly.

Too many unknowns remain, however, to allow for a reliable forecast of the quantity of lithium that will be required for the future EV market. Not only is there the question of whether lithium will be part of the superior EV batteries, but also whether batteries or fuel cells will be the preferred sources of power. In addition, questions as to when and if EVs will make up a significant portion of new car sales in the United States and around the world have been raised. Sales and leases currently lag behind expectations.

Other markets should remain stable with slight growth. Lithium demand could increase dramatically if the technology for nuclear fusion were perfected. This is not expected to take place within the next 25 years and may never occur.

MAGNESIUM

By Deboarh A. Kramer

Domestic survey data and tables were prepared by Jesse J. Inestroza, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

U.S. magnesium production in 2000 dropped by 23% from that of 1999. Much of the production decline came in the second half of the year and was attributed to high energy costs in the Pacific Northwest, which affected Northwest Alloys Inc.'s Addy, WA, primary magnesium plant and a cell relining project that was occurring at the Magnesium Corp. of America (Magcorp) Rowley, UT, plant. The shortfall in domestic production was replaced by imports, which, in 2000, reached their highest level, surpassing the 1999 record high. Canada, China, Russia, and Israel, in descending order, were the principal import sources. China supplied mostly magnesium alloys to the United States, Israel and Russia primarily supplied pure magnesium, and Canada supplied both. Aluminum alloying remained the largest use for magnesium in the United States, and although diecasting remained the second largest use for primary magnesium in the United States, 2000 consumption declined significantly, which was attributed to the overall decline in the U.S. economy.

Noranda Magnesium Inc. began commercial operation of its 63,000-metric-ton-per-year (t/yr) plant in the third quarter of 2000 and planned to have the plant fully operational by the first quarter of 2001. Development work continued on other proposed magnesium plants throughout the world, with the most activity in Australia. If all the plants for which completion dates have been announced are constructed, there would be an additional 96,000 t/yr of capacity in Australia onstream by 2003; 103,000 t/yr in Australia by 2004; 60,000 t/yr in Congo (Brazzaville) by 2005; and 80,000 t/yr in Australia by 2006. If other plants proposed in Australia, Canada, Iceland, and the Netherlands are built, there will be an additional 430,000 t/yr of primary magnesium capacity by the end of the decade.

Legislation and Government Programs

The International Trade Administration (ITA) conducted 5-year sunset reviews of the countervailing and antidumping duties for magnesium from Canada, as is required by the Uruguay Round of Agreements Act. The final determinations in these investigations were that revocation of the order would most likely lead to continuation or recurrence of the duties. For the countervailing duty for pure and alloy magnesium, the likely subsidy was 1.84% ad valorem for Norsk Hydro Canada Inc. and 4.48% ad valorem for all others. The ITA determined that the dumping margin for pure magnesium would be 21.00% ad valorem for Norsk Hydro Canada and all others, the amount at which the duty was originally set (U.S. Department of Commerce, 2000d, e). These sunset decisions may have an adverse effect on Noranda Magnesium. The company completed its 63,000-t/yr primary magnesium plant in Quebec in the third quarter of 2000 and planned to sell the magnesium in the United States. Until the company receives a new shipper review from the ITA, if it requests one, the Magnola plant will be required to pay the antidumping and countervailing duties established for "all others" in these sunset reviews. The

Magnesium in the 20th Century

In 1900, all the magnesium metal used in the United States was imported, mostly from Germany. It was not until 1914, when imports were cut off because of the start of World War I, that the first magnesium extraction plant was built in the United States by General Electric Co. At that time, the principal use for magnesium was in munitions, because it created a bright white light when it was burned, and small quantities were used in flash photography. With the end of World War I, requirements for magnesium decreased, but as new civilian uses were developed, such as use as a scavenger and deoxidizer and as an alloying addition to other metals, production grew steadily. The establishment of the national defense program in 1939, which emphasized the importance of magnesium alloys for aircraft and munitions applications, and the outbreak of World War II soon after, led to a huge increase in magnesium production and consumption in the United States. Between 1940 and 1943, the U.S. Government constructed 13 magnesium plants, and U.S. magnesium production reached its peak in 1943 at 167,000 metric tons. Although most of the plants that had been constructed to supply magnesium for defense needs were closed after World War II, ownership in a few was retained by the Government, and these were reactivated in 1950 during the Korean conflict. In the 1960s and 1970s, U.S. production and use of magnesium grew as use of aluminum grew; magnesium's principal application was as an alloying addition to aluminum. Of particular importance was the introduction of the aluminum beverage can in 1958 and its eventual dominance over steel in this application by about 1980.

By 2000, only two magnesium production plants were operating in the United States, with a total capacity of 83,000 metric tons per year, and imports again supplied a significant portion of the U.S. demand. Magnesium recycled from old magnesium and aluminum alloy scrap also supplied a significant portion of U.S. demand. Aluminum alloying was the largest application for primary magnesium, with about 53%, but structural magnesium alloy components, particularly diecastings, have grown to account for about 23% of the total primary magnesium consumed in the United States. Smaller quantities of magnesium were used for desulfurization of iron and steel and as a reducing agent for other nonferrous metals, such as titanium and beryllium.

Digitized by Google

company could not participate in the June sunset review process because it was not shipping commercial quantities of magnesium to the United States at that time. Through the NAFTA Secretariat, the government of Quebec appealed the final sunset reviews for the antidumping duty on pure magnesium and the antidumping and countervailing duty orders on magnesium alloy that were completed in July. A decision on the appeals was scheduled to be completed by June 15, 2001, (NAFTA Secretariat, [undated], General information, accessed November 7, 2000, at URL http://www.nafta-sec-alena.org/english/index.htm).

In September, the ITA also completed its administrative reviews of countervailing duties for pure and alloy magnesium from Canada for the 1998 calendar year. For this period, the countervailing duty was established at 1.38% ad valorem for magnesium imported into the United States from Norsk Hydro Canada. The ITA also determined that Norsk Hydro Canada had not sold commercial quantities of magnesium into the United States in a 3-consecutive-year period, so the company did not qualify for revocation of the antidumping duty (U.S. Department of Commerce, 2000c). The ITA also began an investigation of countervailing duties for calendar year 1999.

The International Trade Commission (ITC) revoked the antidumping duty order established in 1995 on magnesium imported from Russia because no interested party responded to the April 2000 request (U.S. International Trade Commission, 2000b). In an expedited 5-year review of the antidumping duty established for pure magnesium from China, the ITC determined that revocation of the duty likely would lead to continuation or recurrence of material injury. Therefore, the antidumping duty of 108.26% ad valorem will remain in effect (U.S. International Trade Commission, 2000a).

At the request of Magcorp, the ITA initiated a countervailing duty investigation of pure magnesium from Israel and antidumping duty investigations of pure magnesium from China, Israel, and Russia. The principal material under concern in these investigations is pure magnesium in granular or powder form, which was specifically excluded from earlier antidumping investigations on magnesium from China and Russia. Antidumping duties for other forms of pure magnesium from China and Russia were established in 1995 and remain in effect. This was the first investigation of magnesium imported from Israel. In its preliminary review, the ITA determined that conditions in the magnesium industry have changed since the initial duties were established, and it is appropriate to include granules and powder in the investigations (U.S. Department of Commerce, 2000a, b).

On April 24, 2001, the ITA announced preliminary dumping determinations on U.S. imports of magnesium from China, Israel, and Russia. The preliminary dumping duties on imports from China were determined to be 8.76% ad valorem for Minmetals Precious & Rare Minerals Import and Export/China National Nonferrous Metals Industry Trading Group Corp. and 305.56% for all other companies in China. For Israel, the preliminary dumping duty was determined to be 12.68% ad valorem for Dead Sea Magnesium Ltd. (DSM), and for Russia, the preliminary dumping duty was determined to be 0% ad valorem. The investigation period for China and Russia was April 1, 2000, though September 30, 2000, and the investigation period for Israel was October 1, 1999, through September 30, 2000. The ITA's final determinations are scheduled to be announced by July 9, 2001, for the duties for Russia and Israel and by September 12, 2001, for the duties for China. If these duty determinations are upheld, importers of magnesium from China and Israel will be required to post a bond equal to the percentage margin of dumping (U.S. Department of Commerce, 2001a, b, c).

The U.S. Environmental Protection Agency (EPA) is planning to collect information on sulfur hexafluoride (SF_6) emissions from companies that produce or cast magnesium. The data collection is part of the EPA's SF_6 Emission Reduction Partnership for the Magnesium Industry, which is one of the agency's voluntary programs that contribute to the overall reduction of greenhouse gas emissions. By joining the partnership, a firm agrees to report an estimate of its SF_6 emissions to the EPA annually. The International Magnesium Association will act as the third party by assembling the data and transmitting it to the EPA to protect individual company proprietary data (U.S. Environmental Protection Agency, 2000).

In November, the EPA held an international conference on emission reduction strategies for SF_6. This conference brought together the electric utility and magnesium industries to discuss and learn about a wide array of issues relating to the use, handling, and management of SF_6. Topics particular to the magnesium industry that were discussed included potential replacements for SF_6, SF_6 recycling, and SF_6 leak detection. Presented papers, poster papers, and PowerPoint presentations from the conference were made available at URL http://www.epa.gov/highgwp1/sf6/agenda.html.

One of the replacements that is being investigated is boron trifluoride (BF_3). Hatch Associates, Mississauga, Ontario, Canada, developed a method of in-line generation of BF_3 that minimizes the need to purchase and store the material as a compressed gas, which can be expensive and hazardous. The company claimed that the patented generation process, called MagShield, protects molten magnesium from oxidation, as well as SF_6, with lower consumption rates, at a lower cost, with fewer workplace emissions, and with no fluoride hazardous waste products generated (Revankar and others, 2000).

Production

In 2000, U.S. primary magnesium production declined by 23% from that of 1999 (table 1). Some of the production decrease can be attributed to rising energy costs, particularly in the Pacific Northwest. Aluminum production in this area has also declined, resulting in reduced need for magnesium for aluminum alloying. This mostly affected Northwest Alloys' plant in Addy, WA. In addition, Magcorp had some of its electrolytic cells offline beginning in the fall, because the company was installing new electrolytic technology that should reduce chlorine emissions. Magcorp expected to complete the installation by the fall of 2002 at a cost of $35 million (U.S. Securities and Exchange Commission, September 11, 2000, Renco Metals Inc.—Form 10-Q, accessed June 12, 2001, via URL http://www.sec.gov/edgar.shtml). Because only two plants remain operating, the U.S. Geological Survey (USGS) can no longer publish U.S. production data to avoid disclosing company proprietary data.

Consumption

Aluminum alloying remained the largest end use for primary and secondary magnesium (tables 3, 4). Reported consumption

Digitized by Google

of primary magnesium for aluminum alloying was 53% of the total. Diecasting was the second largest application with 23% of the total reported consumption, and desulfurization of iron and steel ranked third with 12% of the total. In addition to primary magnesium, significant quantities of secondary magnesium are used in iron and steel desulfurization reagents. The total primary magnesium consumed in the United States in 2000 declined by 21% from that of 1999; much of this decline was recorded in the diecasting sector. Although this application continues to be a growth area for magnesium metal consumption, the drop in 2000 was attributed to the overall slowdown in the U.S. economy.

Data for magnesium metal are collected from two voluntary surveys of U.S. operations by the USGS. Of the 81 companies canvassed for magnesium consumption data, 59% responded, representing 40% of the primary magnesium consumption listed in tables 1 and 3. Data for the 33 nonrespondents were estimated based on prior-year consumption levels and other factors. One large nonrespondent accounted for 38% of the 60% of the nonresponse total quantity.

The use of magnesium in automotive applications is continuing to grow. The magnesium content of the 2000 model year North-American-produced vehicles was estimated to be 3.63 kilograms (kg) (8 pounds), a 15% increase from the 1999 model year average of 3.17 kg (7 pounds). Ford Motor Co. planned to continue this growth trend by including magnesium instrument panel support beams in its F-series pickup trucks for the first time. This application was estimated to consume between 5,900 and 8,200 t/yr of magnesium, with each part weighing between 6.8 and 8.2 kg (15 and 18 pounds) each. These would substitute for steel beams in the trucks. Although no specific target year was set for the truck conversion, Ford was beginning to install magnesium alloy instrument panel support beams in the 2001 models of its Explorer sport-utility vehicle (SUV) (Wrigley, 2000d).

Ford announced that it would convert the valve covers on its Triton truck engines to magnesium from plastic, beginning in the 2003 or 2004 model year. The valve covers, which will be made out of AZ91D, will weigh about 3.2 kg (7 pounds). The main reasons for substituting magnesium for plastic are to reduce oil leaks and to improve noise, vibration, and harshness. Ford estimated that about 800,000 engines per year will be used in its pickup trucks, SUVs, and vans, which would consume about 2,500 t/yr of magnesium alloy (Wrigley, 2000b).

Ford also planned to convert the cam covers on some of its truck engines from plastic to magnesium. Beginning with the 2003 model year, Ford will convert the cam covers on its 5.4-liter Triton V-8 engine to AZ91D, and the next model year, the company planned to convert the covers on the 6.8-liter Triton V-10 engine. Estimated magnesium consumption of the cam covers on both engines is about 3,200 t/yr. Spartan Light Metal Products Inc. and Intermet Corp. were expected to be the diecasters for the cam covers. The covers were switched from plastic to magnesium because magnesium has greater creep resistance than the existing plastic covers, and Ford expected that this will lead to fewer service problems (Wrigley, 2000c). With additional parts, such as instrument panel support beams and four-wheel-drive transfer case covers, planned for conversion to magnesium, Ford planned to increase its total magnesium consumption to 78,000 metric tons (t) by the 2004 model year from about 21,000 t in the 2001 model year. Most of the new applications for magnesium will be in the company's SUVs and light-duty trucks (Wrigley, 2000g).

General Motors Corp. (GM) also announced that it would be using about 12 kg (27 pounds) of magnesium alloy diecastings on its new crossover vehicle, the Chevrolet Avalanche, beginning with the 2001 model. The Avalanche is a new type of vehicle that combines the passenger cabin of the Chevrolet Suburban SUV with the cargo box common to pickup trucks. Magnesium components in the new vehicle include four-wheel-drive transfer cases, instrument panel beams, pedal bracket supports, alternator brackets and covers, and the steering wheel armatures (Wrigley, 2000e). In addition, GM was planning to use magnesium alloy support beams in the 2002 models of its new Cadillac roadster model (American Metal Market, 2000).

Lunt Manufacturing Co. entered into a multiyear agreement with GM to manufacture one-piece magnesium alloy instrument panel support beams for the automaker. GM planned to replace the 25-kg (55-pound) steel beams in its 2002 model medium-duty trucks with the magnesium alloy ones, which weigh between 10 and 11 kg (22 and 25 pounds) each. This application was expected to consume 500 to 570 t/yr of alloy AM60. Lunt Manufacturing is only the fourth company in North America that can produce these one-piece beams and will manufacture the components at its Hampshire, IL, facility (Wrigley, 2000j).

For the new 2001 models, North American auto manufacturers were expecting to average between 3.9 and 4.1 kg (8.5 and 9 pounds) of magnesium components per vehicle, a 12.5% increase from the 2000 average. Most of the increase would result from the use of existing part applications in new models. All of the "Big Three" U.S. auto manufacturers (GM, Ford, and DaimlerChrysler Corp.) are using magnesium alloy diecastings in some of their automobiles, trucks, and SUVs. The principal magnesium components will continue to be instrument panel support beams, engine cam covers, four-wheel-drive transfer cases, steering column and pedal bracket supports, and steering wheel armatures (Wrigley, 2000a).

Magnesium also has potential for other automotive applications. GM is interested in a metal hydride fuel cell system using powdered magnesium alloy for its new Precept vehicle, a high-mileage vehicle that uses a combination of electric motors and a small diesel engine. The Precept is the result of the Partnership for a New Generation of Vehicles, a consortium backed in 2000 by $250 million in Federal funding and $980 million from GM, Ford, and DaimlerChrysler. The magnesium-alloy-metal hydride fuel system was developed by Energy Conversion Devices Inc.'s subsidiary Ovionics Battery Co. Because the hydrogen is stored as a solid rather than as a gas or liquid, the need for large storage tanks is eliminated (Wrigley, 2000i; Energy Conversion Devices Inc., [undated], Ovonic hydrogen generation, accessed at URL http://www.ovonic.com/hydrogen/technology.html).

Magnesium also was being used for large components in concept and limited-production vehicles. BMW AG of Germany equipped its Z22 concept car with a cast magnesium cylinder block. Saleen Inc., a specialty vehicle manufacturer based in California, created a high-performance, light-metals-intensive production car called the S7. Magnesium is used in engine components in the vehicle, along with such materials as beryllium and titanium. Only 300 to 400 vehicles were expected to be produced over the 4-year production run (Light Metal Age, 2000). DaimlerChrysler was also using significant quantities of magnesium in its ESX3 concept hybrid-electric

Digitized by Google

family vehicle. Magnesium components were substituted for steel as a radiator enclosure, as an instrument panel support beam, and as A pillars (Wrigley, 2000f).

The Swiss ferroalloys producer Xstrata AG announced that it reached an agreement to acquire the Magnesium Services International fluxless magnesium recycling technology, which produces secondary magnesium diecasting alloys using 100% scrap as the feed material. As a result, Xstrata has begun a feasibility study on the construction of a 25,000-t/yr magnesium recycling plant in the Midwestern United States (Platt's Metals Week, 2000g).

TAC Manufacturing Inc., a subsidiary of the Japanese firm Tokai Rika Co., announced that it would install magnesium casting equipment at its existing facility in Jackson, MI, to produce magnesium steering wheel locks. The cost of the new equipment was estimated to be about $10 million. The company already supplied steel and zinc automotive parts to Toyota Motor Corp.'s auto manufacturing plants in the United States. The company planned to sell the magnesium parts to Toyota, as well as other U.S. manufacturing firms (Furukawa, 2000b).

Stocks

Producers' yearend 2000 stocks of primary magnesium declined slightly from those at yearend 1999; these data cannot be reported to avoid disclosing company proprietary data. Consumer stocks of primary and alloy magnesium increased to 7,550 t at yearend 2000 from 6,980 t at yearend 1999. Yearend 2000 consumer stocks of secondary magnesium increased to 2,360 t from the 1999 level of 783 t (revised).

Prices

Quoted magnesium prices declined during 2000, reflecting the oversupply of magnesium in the world market. The Metal Bulletin free market price range for pure magnesium started the year at $2,450 to $2,550 per metric ton and dropped to $1,900 to $2,000 per metric ton by yearend. The China free market price range declined from $1,520 to $1,570 per metric ton to $1,300 to $1,310 per metric ton by yearend.

Platt's Metals Week's European free market price decreased from a range of $2,250 to $2,350 per metric ton at the beginning of the year to $1,800 to $2,000 per metric ton by yearend. The Platt's Metals Week U.S. spot western price dropped from a range of $1.40 to $1.45 per pound at the beginning of 2000 to $1.23 to $1.30 per pound at yearend. The Platt's Metals Week U.S. spot dealer import price decreased from a range of $1.25 to $1.32 per pound at the beginning of the year to $1.05 to $1.15 per pound by yearend.

Foreign Trade

Total magnesium exports for 2000 were about 18% lower than those in 1999 (table 5). Canada (63%), the Netherlands (12%), and Mexico (8%) were the main destinations. Imports for consumption in 2000 were slightly higher than those in 1999 (table 6), and continued to reach new high levels. Canada (40%), China (24%), Russia (15%), and Israel (9%) were the principal import sources in 2000. Russia, Israel, and Canada, in descending order, were the principal sources of imported metal. Canada and China were the principal sources of imported alloys.

World Review

According to figures published by the International Magnesium Association (IMA), world magnesium shipments in 2000 were 367,000 t, which was slightly lower than those of 1999. The data, however, are not exactly comparable; in 1999, the IMA includes shipments of recycled diecasting scrap by the primary producers, and these data were not included in 2000. Aluminum alloying, with 45% of total shipments, was the largest end-use category for magnesium, followed by diecasting with 30% and desulfurization with 14%. Yearend 2000 world inventories increased slightly to 46,500 t representing an estimated 45 days of supply, based on the previous 12 months of shipments (International Magnesium Association, 2001).

After an investigation that began in June 1999, the European Commission recommended an antidumping duty of 63.4% on imports of magnesium from China. This was a significant increase from the 31.7% that has been in effect since 1998 (Platt's Metals Week, 2000e). The Chinese producers were expected to appeal this duty, although several producers reportedly sold magnesium at prices lower than the Chinese Magnesium Association's minimum reference price of $1,500 per metric ton (Platt's Metals Week, 2000c).

Australia.—In March, Australian Magnesium Corp. Ltd. (AMC) completed its feasibility study on construction of a new magnesium plant in Stanwell, Queensland. The study estimated that capital costs for a 96,000-t/yr plant would be $759 million and that operating costs would be between 58.1 and 63.8 cents per pound. (The range in operating cost is based solely on varying exchange rates between Australian and U.S. dollars.) Under a restructuring proposal, Queensland Metals Corp. Ltd. (QMC) will acquire Normandy Mining Ltd.'s 50% interest in AMC in exchange for 225 million shares of QMC. Once a commitment to commercialization of the AMC magnesium plant is made, these shares will be distributed to Normandy's shareholders (Queensland Metals Corp. Ltd., March 28, 2000, AMC feasibility study completed, accessed April 25, 2000, via URL http://www.normandy.com.au; Queensland Metals Corp. Ltd., April 5, 2000, AMC ownership optimised, accessed April 25, 2000, via URL http://www.normandy.com.au).

AMC entered into an alliance with VAW Aluminium AG to develop a magnesium engine block in hopes of providing additional funding for AMC's proposed magnesium plant. If the magnesium engine block is commercialized, AMC would be VAW's exclusive supplier of magnesium alloy for the first 5 years of production. AMC already has a 45,000-t/yr offtake agreement with Ford that provides much of the financing for its pilot plant (Metal Bulletin, 2000a). The company also received all governmental and environmental approvals for the construction of a commercial plant and expected that the plant would come onstream in 2003 (Metal Bulletin, 2000b).

Australia's Commonwealth Scientific and Industrial Research Organisation (CSIRO) and the Queensland government each planned to contribute $A50 million to assist Australia's fledgling magnesium industry. CSIRO's contribution would assist in the commercialization of AMC's process technology, and the Queensland government's contribution would be used to develop a light-metals industry precinct in Stanwell. The Stanwell Energy Park was expected to be developed over the next decade to include magnesium production, diecasting, chemical, and associated service industries (Australian Magnesium Corp. Ltd., November 14, 2000, $100 million

Digitized by Google

Federal & Queensland government commitment, accessed December 9, 2000, via URL http://www.austmg.com). AMC also planned to outsource its research and development activities to CSIRO as part of a 4-year agreement. The new agreement covered two major research areas—improving primary magnesium process technologies and developing new value-added applications and improved methods for producing magnesium components, such as alloys, casting, melt, and recycling systems (Australian Magnesium Corp. Ltd., December 7, 2000, AMC to contract CSIRO in research & development alliance, accessed December 9, 2000, via URL http://www.austmg.com).

Pima Mining NL reported that it raised $3.5 million for further development of a proposed magnesium plant by placing 18.2 million shares to institutional investors. The company, through its 80%-owned SAMAG Ltd. subsidiary, planned to construct a 52,500-t/yr primary magnesium plant in Port Augusta, South Australia, using technology acquired from Dow Chemical Co. SAMAG was in the final stages of selecting design engineers and construction contractors. An earlier feasibility study for the project indicated that the capital cost for the plant would be $375 million, and the operating cost would be less than 60 cents per pound of magnesium (Metal Bulletin, 2000j).

In May, SAMAG began trial mining of its magnesite deposit in South Australia. The company planned to mine about 2,000 t of ore for trial leaching tests. The company selected Port Pirie as the site for its proposed 52,500-t/yr magnesium plant because of its existing infrastructure (the Pasminco zinc smelter is located at the same site), rail link between Port Pirie, and the location of the magnesite raw material near Leigh Creek. Initial investment in the plant was expected to begin in 2001, with commercial production scheduled for 2004 (Metal Bulletin, 2000k).

SAMAG purchased the Myrtle Springs and Huandot magnesite deposits from Unimin Australia Ltd., which increased SAMAG's total magnesite resources in the Leigh Creek area in the Northern Territory to 579 million metric tons. This magnesite would provide additional resources for its planned magnesium plant (Pima Mining NL, November 28, 2000, SAMAG purchases additional magnesite resources, accessed January 8, 2001, at URL http://www.pima.com.au/temp.asp?t=asx28nov00). The company also entered into a long-term sales agreement with Germany's ThyssenKrupp Metallurgie GmbH for all of SAMAG's proposed output of magnesium metal and alloys. The agreement allowed SAMAG to receive a guaranteed base price that is sufficient to service the project's debt finance requirements (Pima Mining NL, November 16, 2000, SAMAG signs metal sale agreement with German industrial giant Thyssen Krupp, accessed November 28, 2000, at URL http://www.pima.com.au/temp.asp?t=asx16nov00).

The Council for Minerals Technology (Mintek) of South Africa planned to test a new magnesium production process at a pilot plant that was scheduled to start operation by yearend. The new process is a derivative of the Magnetherm process in which dolomite is reduced with ferrosilicon and alumina to produce magnesium vapor. In Mintek's process, the process is carried out at atmospheric pressure at about 1,700° C compared with operating at a vacuum at 1,550° C to 1,600° C for the Magnetherm process. By operating at atmospheric pressure, rather than in a vacuum, the reduction process can be carried continuously, rather than as a batch process, which may have economic advantages. Mintek planned to evaluate the process for 3 to 6 months before deciding if it is suitable for commercial-scale development and estimated that a 50,000-t/yr plant would require a capital investment of $200 to $250 million (Metal Bulletin, 2000l). Immediately after this announcement, Mintek signed a technology license agreement with Australia's Mt. Grace Resources NL, whereby Mt. Grace Resources would fund the demonstration project and, if test work was successful, use the process to recover magnesium from its Batchelor magnesite deposit in the Northern Territory. Mt. Grace Resources planned to test the new process along with the Heggie aluminothermic process to determine which would be the more economically attractive (Mt. Grace Resources NL, October 6, 2000, Mintek magnesium production technology licence and project option agreement, accessed October 17, 2000, at URL http://www.mtgrace.com/releases/oct_6_2000.html).

In October, Mt. Grace Resources began bulk magnesite mining operations at its Batchelor magnesium project. The company planned to mine and stockpile 2,000 t of magnesite to provide sample material for test work. An ore parcel was scheduled to be sent to Mintek in Johannesburg in January 2001 for testing (Mt. Grace Resources NL, October 30, 2000, Mt[.] Grace Resources mines ore at Batchelor, accessed November 8, 2000, at URL http://www.mtgrace.com/releases/oct_30_2000.html). Mt. Grace Resources planned to complete a 50,000-t/yr magnesium plant by 2004.

Golden Triangle Resources NL produced its first magnesium metal in November. The company is using serpentinite tailings from the former Woodsreef Mine in New South Wales as feedstock. Golden Triangle also announced the development of a new electrolysis system, for which it has applied for a patent. According to the company, the new system will combine magnesium chloride dehydration, electrolyte purification, and electrolysis in one apparatus. Additionally, the apparatus will include the preparation of magnesium alloys. The new electrolytic system, which was developed by the Joint Israeli-Russian Laboratory for Energy Research at Ben Gurion University, will also have the added advantage of significant energy savings in the magnesium production process (Golden Triangle Resources NL, November 28, 2000, Re: Revolutionary new magnesium electrolyzer, accessed January 8, 2001, at URL http://www.goldentriangle.com.au/28Nov00.htm). Golden Triangle Resources planned to construct an 80,000-t/yr plant by 2006.

Canada.—In spite of a fire in one of the four electrolytic cells on August 12, Noranda Magnesium planned to open its Magnola magnesium plant in Quebec by the first quarter of 2001. Noranda produced its first magnesium metal late in October, and 2 out of 24 electrolytic cells had been commissioned. When the 63,000-t/yr plant opens, it will be the first in the world to use asbestos tailings as a raw material for magnesium production (Platt's Metals Week, 2000h; Canada Newswire, October 25, 2000, Noranda produces first magnesium metal, accessed October 31, 2000, at URL http://newswire.ca/releases/October2000/25/c6547.html).

Cassiar Magnesium Inc. (formerly Cassiar Mines & Metals Inc.) expected to complete a feasibility study on its planned magnesium project by the end of 2000. The company hopes to construct a 90,000-t/yr primary magnesium facility in British Columbia by 2003. Cassiar Magnesium planned to present the

Digitized by Google

study results to Aluminium of Korea Ltd. (Koralu), with which it has a memorandum of understanding for an initial investment. If, after assessing the study results, Koralu opts to fund the $600 million project, it would have the option to acquire a 65% stake in the plant (Metal Bulletin, 2000d).

Meridian Technologies Inc. was planning to construct its second magnesium diecasting facility in Strathroy, Ontario, which would bring the company's total number of facilities to four. In addition to the two plants in Ontario, Meridian operates plants in Eaton Rapids, MI, and Verres, Italy. Capacity at the new facility is estimated to be 5,000 t/yr of AZ91D and the AM series of alloys (Wrigley, 2000h).

China.—Norsk Hydro A/S announced that it would build a magnesium alloy facility in China. Production capacity of the plant will be 5,000 t/yr, and it will use magnesium produced in China as the feed material. Norsk Hydro planned to have the plant, which will be located in Xian, operational by early 2001. Alloy ingot produced at the plant was expected to be marketed to Norsk Hydro's customers throughout the world (Norsk Hydro A/S, April 20, 2000, Hydro Magnesium goes to China, accessed April 21, 2000, via URL http://www.hydro.com). In addition, Norsk Hydro Magnesiumgesellschaft mbH planned to build a magnesium anode facility in China at the same site. Initial production capacity was expected to be 400 t/yr, perhaps expanding to 800 t/yr. The principal market for the anodes is hot-water heaters in China and Southeast Asia. No timetable was given for plant startup (Norsk Hydro A/S, April 25, 2000, Magnesium in China—Step two, accessed July 7, 2000, via URL http://www.hydro.com).

Because of pollution problems and weak prices, many small magnesium plants in Henan and Shanxi Provinces closed by September. Some of the larger plants were expected to close for a short period to make process upgrades to reduce pollution. The Chinese magnesium export market was reported to be slow, particularly to countries in Europe because of the potential of higher antidumping duties (Metal Bulletin, 2000e). In spite of the world oversupply and plant closures, Chinese magnesium producers continued to announce production expansions at some plants. Yinguang Magnesium Industry Group's new 5,000-t/yr expansion was expected to be completed in December; this would bring the plant's total capacity to 20,000 t/yr of magnesium and magnesium alloy. Shanxi Top Magnesium Co. planned to increase its capacity by yearend 2000 to about 10,000 t/yr from 7,200 t/yr (Platt's Metals Week, 2000j).

The Ningxia Magnesium Metal Works was declared bankrupt in September. Production at the 1,400-t/yr plant had stopped in March 1999, and the state was planning to auction off the plant once the final auditing was complete (Platt's Metals Week, 2000a). Tongxiang Magnesium Industry Co. halved its magnesium output for the second half of 2000, according to company officials. The cutback, to 1,000 metric tons per month (t/mo) from 2,000 t/mo, was in response to declining prices. Tongxiang exported most of its product to Japan and to the Republic of Korea (Platt's Metals Week, 2000i).

An official from the Chinese Magnesium Association stated that China planned to construct a 50,000-t/yr magnesium plant in Qinghai by 2005 using the salt lake resources in the area as feedstock. New plant construction would be funded by the Government and by Minhe Magnesium Co., which operated a 7,000-t/yr magnesium plant in the province (Platt's Metals Week, 2000b). This plant, if constructed, would be China's largest individual plant.

Czech Republic.—Magnesium Elektron, a unit of the Luxfer Group, selected a site northwest of Prague to build a 10,000-t/yr secondary magnesium plant. An unoccupied manufacturing plant was located at the site, and Magnesium Elektron planned to refurbish the building for use as a magnesium recycling plant. The new plant, which will use magnesium alloy scrap from Germany as its feedstock to produce casting alloys, is expected to begin commercial operation in mid-2001 at an initial operating capacity of 7,500 t/yr. The finished product will be exported to German customers, and the plant will gradually ramp up its capacity to 10,000 t/yr by 2002, with an option to increase to 20,000 t/yr if the market warrants it (Metal Bulletin, 2000h).

Israel.—The Board of Directors of Israel Chemicals Ltd. approved the transfer of a majority stake (65%) in DSM from Dead Sea Works Ltd. to Israel Chemicals, the parent company, at a cost of $66.3 million; Volkwagen AG of Germany owns the remaining 35%. Israel Chemicals also would absorb DSM's $111 million in bank debts (Platt's Metals Week, 2000f).

In March, DSM was qualified by DaimlerChrysler to supply magnesium alloys AZ91D, AM50A, and AM60B for use by all of the company's diecasters and was in the initial stages of negotiating with GM to supply it with magnesium alloys. DSM also was in the process of increasing production at the facility in 2000 to 30,000 t of magnesium metal and 24,000 t of magnesium alloys, and the company was proceeding with the construction of its direct-chill caster for producing magnesium T-bar ingot (Platt's Metals Week, 2000d).

Japan.—Japan's Nippon Kinzoku Co. Ltd. completed a 2,400-t/yr magnesium recycling plant in Kitakami, Iwate Prefecture, that was expected to begin commercial production in January 2001. The completion of this plant raised the company's total recycling capacity to 8,000 t/yr. Nippon Kinzoku operated three other magnesium recycling plants in Japan (Furukawa, 2000a).

Netherlands.—A preliminary feasibility study on the Antheus Magnesium Development Programme Delfzijl proposed magnesium plant in the Netherlands was completed. The study was for a combined magnesium smelter, diecasting plant, and recycling plant, all at the same location. Projected capacity of the magnesium smelter would be 15,000 t/yr, with potential expansion to 30,000 t/yr. With the projected sale of excess chlorine generated at the plant, operating costs for the plant were estimated to be about 60 cents per pound. A feasibility study was expected to be completed by early 2001, and a decision on plant construction was expected by the end of 2001 (Brooks, 2000).

Russia.—Russia's Uralasbest, the country's largest asbestos producer, announced that it planned to construct a 50,000-t/yr primary magnesium plant using tailings from the company's asbestos production as its magnesium source. Uralasbest reportedly has constructed a pilot plant based on technology developed at the Solikamsk magnesium plant to recover the magnesium from the tailings, which contain about 24% magnesium. The cost of building a commercial-scale plant was estimated to be about $300 million, and the regional government was planning to issue recommendations on the proposal (Interfax Mining & Metals Report, 2000b).

The European Bank for Reconstruction and Development planned to grant $95 million to the Solikamsk magnesium plant by the end of 2000. The grant was targeted toward increasing

Digitized by Google

magnesium production by 100% in 2001. In 1999, Solikamsk produced 9,000 t of primary magnesium and 9,200 t of magnesium alloys (Interfax Mining & Metals Report, 2000a).

Serbia and Montenegro.—The 5,000-t/yr primary magnesium plant in Serbia reportedly restarted production at the end of 1999. The plant had been shut down because of the NATO bombing in the area. Although small quantities of magnesium were produced, it was uncertain whether commercial quantities of magnesium would be produced again (Metal Bulletin, 2000i).

Taiwan.—Norsk Hydro and Taiwan's CS Aluminium Corp. were discussing the construction of a magnesium recycling plant in Taiwan. Although the project was in the planning stage and no details were disclosed, the project was expected to collect magnesium diecasting scrap from Taiwanese firms and recover it in the form of high-purity alloys (Metal Bulletin, 2000f).

Taiwan's Sheng Yu Steel Co. announced that it would complete construction of a magnesium alloy casting plant in Pingnan by early 2001. The plant will produce magnesium alloy covers for computer laptops, digital cameras, and electronic appliances (Metal Bulletin, 2000c).

Ukraine.—MMD-Mineral hoped to restart the Kalush magnesium plant, which had been idle since 1998. The 10,000-t/yr plant had operated using byproduct magnesium chloride salt from a nearby fertilizer operation as its raw material before it closed because of lack of raw material and high operating costs. MMD-Mineral planned to use bischofite ($MgCl_2 \cdot 6H_2O$), which it extracted at a nearby operation, as an alternative raw material source and use technology similar to that used by DSM in Israel. Much of the magnesium plant was owned by the Ukrainian Government, and tender for the magnesium plant, which needed about a $50 million investment for refurbishment, was expected sometime in 2001 (Metal Bulletin, 2000g).

Current Research and Technology

Noranda developed a new family of magnesium alloys with elevated temperature properties equal to or better than those of the magnesium alloy AE42, which can be sold at a lower cost. Unlike AE42, which normally is used in aerospace applications and contains expensive rare earth elements, the new alloys contain magnesium, 5% aluminum, an unspecified quantity of strontium, which is added to improve heat resistance, and a small quantity of manganese, which is added for corrosion resistance. According to Noranda, these alloys demonstrated excellent creep and mechanical properties between 150° C and 175° C and had salt-spray resistance equivalent to that of AZ91D and of the AM series of magnesium alloys. Because of the enhanced properties, the new alloys could be suitable for automotive applications such as automatic transmission casings, engine fan components, oil pumps, and oil pans (Advanced Materials & Processes, 2000b; Pierre Labelle, Mihriban Pekguleryuz, Don Argo, Mike Dierks, Todd Sparks, and Ted Waltematte, [2001], Heat resistant magnesium alloys for power train applications, accessed June 18, 2001, at URL http://www.my.noranda.com/NR/rdonlyres/00001d27cvfandndmjmzqeci/HeatResistantMgAlloys1.pdf).

At Honda Motor Corp., researchers also developed a creep-resistant magnesium alloy for use in oil pans in the engines of Honda's hybrid cars. The new alloy ACM522 also uses a magnesium/5%-aluminum alloy as the basic constituent, but contains 2% calcium, 2% cerium mischmetal, and 0.3% manganese. This new alloy has creep resistance characteristics that are superior to AE42 and has resistance to both heat and corrosion that are similar to those of aluminum alloy A384. Magnesium oil pans made from this alloy are 35% lighter than the aluminum ones that they replace (Kioke and others, 2000).

Researchers at Pacific Northwest National Laboratories and Thixomat Inc. developed a casting process for a series of magnesium-zinc-aluminum-calcium alloys that demonstrates high creep resistance at temperatures up to 175° C. Although this family of alloys has demonstrated improved high-temperature properties, it has exhibited castability problems when it is die-cast. To alleviate this problem, the alloys were cast by the Thixomolding process, then evaluated for creep resistance, moldability, and tensile and compressive strengths. Thixomolding is a patented high-speed injection molding of semisolid thixotropic alloys, which yields high-quality, net-shape magnesium components (Advanced Materials & Processes, 2000c).

Scientists at Wright-Patterson Air Force Base were developing new aluminum-magnesium-scandium alloys for aerospace applications to replace titanium in certain components. By developing high-temperature aluminum alloys, the cost and lead time for the parts could be reduced. Magnesium is present in the alloys because of its strengthening capability. The alloys were in the initial stages of development (Advanced Materials & Processes, 2000a).

Researchers at Bar-Ilan University in Israel announced the construction of the first rechargeable battery based on magnesium. According to the researchers, the new battery can be charged more than 2,000 times and produces up to 1.3 volts of power, which is similar to existing rechargeable batteries. Although magnesium batteries already exist, they are used mostly in military applications and are not rechargeable. By using electrolyte solutions based on magnesium organohaloaluminate salts and $Mg_xMo_3S_4$ (where x is between zero and one) cathodes, the researchers can produce a battery that is about the size of a computer monitor. The new batteries were expected to be commercially available within a year and to be used as uninterrupted power supplies for computer networks affected by power outages (Aurbach and others, 2000).

The French producer of magnesium casting systems Brochot SA developed a new casting wheel designed to minimize surface oxidation when casting magnesium and magnesium alloys. The company applied for a patent of its design, which was adapted from the design of a casting wheel for aluminum systems. By redesigning the points at which the molten metal is delivered to the casting wheel, metal turbulence is reduced, thus minimizing the surface area available for oxidation. In addition, Brochot has replaced the SF_6 protective cover gas with a patented mixture of carbon dioxide, argon, and xenon (Brown, 2000).

Ford was sponsoring research, through the Department of Commerce's Advanced Technology Program, to develop an innovative magnesium diecasting process to be used to cast large components from magnesium alloys. The objective of the 4-year project was to develop a multiport injection "hot runner" system for introducing magnesium into die cavities at a controlled temperature and flow rate. The new process is expected to increase yields and reduce scrap by 10%, thus lowering diecasting production costs (National Institute of Standards, October 2000, Cost-reduced magnesium die castings

Digitized by Google

using heated runners (CORMAG), accessed January 26, 2001, at URL http://www.nist.gov/public_affairs/atp2000/00004334.htm).

In May, the IMA selected the Foundation of Scientific and Industrial Research at the Norwegian University of Science and Technology to conduct research on alternative materials for SF_6 in magnesium production and casting operations. The proposed activities of the research team include evaluating the performance characteristics of recently proposed alternatives and seeking out and testing new alternatives, evaluating the addition of minor elements on protective film formation, and optimizing delivery of the most promising alternatives. Research progress will be openly reported to benefit the entire magnesium industry and will be reported annually at the IMA meeting (U.S. Environmental Protection Agency, November 20, 2000, SF_6 and the environment—Understanding, measuring, and managing, accessed June 15, 2001, via URL http://www.epa.gov/highgwp1/sf6/agenda.html).

Outlook

Although magnesium alloy diecasting applications continue to be a growth area for the use of magnesium in the United States, magnesium most likely will remain in an oversupply situation. Growth in diecastings will be offset by some declines in other applications. Aluminum alloying applications in the United States are likely to decline in the near term. High energy prices in the Pacific Northwest, where the most significant portion of the U.S. aluminum production is located, and increased demand for power in California have caused temporary closure of a significant portion of the aluminum production capacity. By yearend 2000, companies announced the temporary closure of 1.03 million metric tons per year (Mt/yr) of capacity, almost two-thirds of the smelters' engineered capacity of 1.64 Mt/yr (CRU International Ltd., 2001). Although some of this capacity may return to operation as energy prices decline, U.S. aluminum production will probably decline in 2001. Through March 2001, U.S. primary aluminum production was 27% less than that in the same period of 2000; comparing the same periods, secondary aluminum recovery from new and old scrap also declined by 12% (Plunkert, 2001). As a result of this projected decline in U.S. aluminum production, magnesium use in this, its largest application, is also projected to decline.

Potential new capacity from proposed plants in Australia that is scheduled to come onstream within the next 5 years could also add to the oversupply situation that has developed. Because of this proposed capacity, capacity at smaller, older plants is being reevaluated. Alcoa Inc. announced that it would close its Northwest Alloys plant by October 31, 2001, citing high production costs and unfavorable market conditions (Alcoa Inc., June 22, 2001, Alcoa shuts down Northwest Alloys magnesium smelter, accessed July 2, 2001, at URL http://www.alcoa.com/site/news/news_release/73157-2001_06_22.asp). Pechiney announced that it may close its 17,000-t/yr primary magnesium plant in Marignac, France. Although no final decision has been made, the company was claiming that competition from low-priced imports of Chinese magnesium led to heavy financial losses at its plant for the past 2 years (Metal Bulletin, 2001). In the short term, closure of these plants, particularly the U.S. plant, is likely to lead to increases in imports from such areas as China and Russia. In the longer term, the elimination of some suppliers may provide additional customers for the proposed plants; this increases the likelihood of more of these new plants actually being constructed.

MAGNESIUM COMPOUNDS

By Deborah A. Kramer

Domestic survey data and tables were prepared by Jesse J. Inestroza, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Although U.S. production of magnesium compounds in 2000 decreased from that in 1999, apparent consumption increased by about 7%. Production of dead-burned magnesia decreased by about 9%, mainly as a result of the closure of a plant in California, but net imports increased by 36%. Caustic-calcined magnesia production declined by about 4%, and net imports remained about the same. Of the total U.S. magnesium compounds production, about 60% came from seawater and well and lake brines. The remainder was recovered from magnesite, dolomite, olivine, and brucite. About 69% of the total consumption of magnesium compounds was for refractory applications. The remaining 31% was used in agricultural, chemical, environmental, and other applications.

Production

In 2000, domestic production of caustic-calcined magnesia declined slightly from that in 1999. U.S. production of dead-burned magnesia dropped by about 9% from that in 1999, mostly because of the closure of National Refractories and Minerals Corp.'s Moss Landing, CA, plant (table 3).

Data for magnesium compounds were collected by the U.S. Geological Survey from one voluntary survey of U.S. operations. Of the 17 operations canvassed, 71% responded, representing 65% of the magnesium compounds shipped and used (table 3). Data for the five nonrespondents were estimated on the basis of prior-year consumption levels and other factors.

Two companies in the United States produced olivine—Unimin Corp. and Olivine Corp. Unimin operated two mines, one in North Carolina and one in Washington, and processing plants in Indiana, North Carolina, and Washington. Olivine operated one mine and one processing plant in Washington.

Fused magnesia was produced by two companies in the United States—Newminco Inc. with a plant in Midway, TN, and Universal Ceramic Materials plc of the United Kingdom, which operated a plant in Cherokee, AL, through its Muscle Shoals Minerals Inc. subsidiary. The Tennessee plant had been owned by English China Clays International Ltd., which was required to sell the plant when it was acquired by Imerys (formerly Imetal). The plant was sold in June 2000 (Imerys, 2001, Annual report 2000, accessed May 17, 2001, via URL http://www.imerys.com).

The largest magnesite production facilities in the world are in China, North Korea, and Russia. Together, these three countries account for 68% of the world magnesite production capacity. Japan and the United States account for 54% of the world's magnesium compounds production capacity from seawater or brines. Fused magnesia is produced in Australia, Brazil, Canada, China, Israel, Japan, the Republic of Korea,

Magnesium Compounds in the 20th Century

Deposits of magnesite (magnesium carbonate) had been discovered in California in 1886, and by 1910, output of the ore from mines in Santa Clara County had reached 12,000 metric tons per year. Most of the ore was calcined and used by the manufacturers of paper in California and Oregon to treat wood pulp. In 1913, production of magnesia by precipitation of dolomite began in Pennsylvania, and in 1917, mining of magnesite began in Stevens County, WA. Imports of magnesite from Europe, which had been the dominant supplier to the United States, were cut off during World War I. Mining of the magnesite in the Nye County, NV, deposit began in 1937. At the outbreak of World War II, production of magnesian ores in the United States was accelerated to provide material not only for basic refractories but for magnesium metal as well. During World War II, almost 1 million metric tons of magnesite was mined and used to produce magnesium metal. Development of techniques to produce magnesium compounds other than magnesia, however, progressed slowly in the United States. By the end of 1959, more than 13 million tons of magnesite had been taken from the mines in the United States, but the deposits of easily recoverable magnesite in California had been worked out by 1950. In 1956, a broad expansion program began in the basic refractories industry in the United States. This included building new magnesia and basic-brick plants and installing new rotary kilns to burn dolomite, as well as improving and expanding production facilities already in operation. The greatest increase in production capacity was in plants to recover magnesia from seawater and brines. This production, which amounted to less than 40% of total domestic output in 1947, rose gradually to 66% in 1959. Domestic capacity for producing other magnesium compounds continued to increase steadily after World War II. Production of magnesium compounds in the United States peaked in 1966 and trended downward since then as imports replaced domestic production.

By 2000, only one magnesite mine was in operation in the United States in Nye County, NV. Magnesia and other magnesium compounds were produced from seawater at plants in Delaware and Florida, from well brines in Michigan, and from brines from the Great Salt Lake in Utah. Imports of magnesia, mainly from China, supplied about 48% of the total U.S. apparent consumption of magnesium compounds. About 69% of the magnesium compounds consumed in the United States was used for refractories. The remaining 31% was consumed in agricultural, chemical, construction, environmental, and industrial applications. U.S. imports for consumption continued to increase significantly in 2000.

Digitized by Google

Mexico, Russia, the United Kingdom, and the United States. World production capacity is estimated to be about 650,000 metric tons per year (t/yr), with about 500,000 t/yr of capacity in China (Pearson, 2000).

Norway is the world's principal producer and supplier of olivine. Other producers include Australia, Italy, Japan, Mexico, Pakistan, Spain, and the United States.

In August 2000, Premier Services Inc. increased the caustic-calcined magnesia capacity at its Gabbs, NV, magnesite facility by 20,000 t/yr to 140,000 t/yr. The capacity increase was in response to growing demand in the wastewater treatment market. About $1 million was spent on an incremental furnace expansion, and Premier Services said that the company may expand further in 2001 if the growth in the market continues (North American Minerals News, 2000c).

Aurora Partners Ltd. of the United States announced that it would form a joint venture with North Korea's Korea Magnesite Clinker Industry Group to mine, process, and ultimately export magnesia products from North Korea. This would be the first joint venture between U.S. and North Korean firms. Although North Korea has been allowed to export magnesite to the United States since 1995, no material has entered since then. An embargo preventing U.S. firms from establishing joint ventures with North Korean companies was lifted in June 2000 (North American Minerals News, 2000a).

Near the end of the year, the State of Utah began modifying the salinity levels in the Great Salt Lake by deepening a causeway opening by more than 2.4 meters (8 feet). The railroad causeway in the lake has been acting as a dam and creating essentially two separate bodies of water with different salinity levels. Deepening the breach in the causeway would allow for greater water flow between the two bodies, thereby equalizing the salinity levels. Although it could be 3 to 5 years before the effects of the causeway modifications are known, this could adversely affect companies that recover magnesium chloride from the higher salinity portion of the Great Salt Lake (Green Markets, 2001).

As part of RHI AG's 1999 acquisition of Global Industrial Technologies Inc., which was the parent company of Harbison-Walker Refractories Inc., RHI was required by the U.S. Federal Trade Commission (FTC) to divest itself of some of its assets. According to a consent agreement, RHI would be required to divest two refractory manufacturing plants in North America as well as assets related to certain refractory products produced at a third North American location. The divestiture was agreed to because, after the merger of RHI and Global, the two companies combined would control about 95% of the $30 million North American market for magnesia-carbon bricks for basic-oxygen furnaces (BOFs) used in the steelmaking industry. In addition, the merged company would hold 65% of the $58 million market for magnesia-carbon bricks for electric-arc furnaces, 40% of the $100 million market for magnesia-carbon bricks for steel ladles used with BOFs, 70% of the $50 million market for high-alumina bricks for steel ladles used with BOFs, 50% of the $23.5 million market for high-alumina bricks for torpedo cars, and 46% of the $5 million market for magnesia-chrome bricks for steel degassers. As a result of its market dominance in these sectors, the FTC ordered RHI to sell to Resco Products Inc. two magnesia-chrome-brick-producing plants (one in Hammond, IN, and one in Marelan, Quebec, Canada) and specific assets related to the production of high-alumina bricks at its Farber, MO, plant. Resco manufactures similar refractory products, but does not compete in the same markets (U.S. Federal Trade Commission, December 30, 1999, FTC clears proposed acquisition of Global Industrial Technologies by RHI AG, accessed March 14, 2001, at URL http://www.ftc.gov/opa/1999/9912/rhi1.htm).

Consumption

In 2000, environmental applications (water treatment and stack gas scrubbing, in descending order) consumed the most caustic-calcined magnesia, accounting for 41% of U.S. shipments; this was a 4% increase from the 1999 total. The following categories, with the individual components in descending order of consumption in parentheses, were the other end-use sectors for caustic-calcined magnesia: chemical, 34%; agriculture (animal feed and fertilizers), 18%; construction (primarily oxychloride and oxysulfate cements), 3%; manufacturing (rubber, fuel additives, and electrical), 3%; pharmaceuticals and nutrition (sugar, medicine and pharmaceuticals, and cosmetics), less than 1%; and unspecified uses, less than 1%.

Magnesium carbonate was used principally as a chemical intermediate, in medicines and pharmaceuticals, in rubber processing, and in cosmetics (uses are given in descending order of quantity). Magnesium hydroxide was used mainly in the chemical industries and for water treatment. Magnesium sulfate was used mostly for animal feed, pulp and paper, chemical, electrical, and pharmaceutical applications. Magnesium chloride was used mainly as a chemical intermediate and in pharmaceuticals. Magnesium chloride brines were used principally for road dust and ice control and as a chemical intermediate.

Foundry uses remained the largest application for olivine in the United States, accounting for 87% of consumption of domestically produced material. Refractory applications accounted for 7% of U.S. consumption, and sandblasting and other abrasive uses accounted for 6%.

Prices

Yearend 2000 prices for magnesium compounds quoted in Chemical Market Reporter and Industrial Minerals remained the same as those for 1999 (table 4).

Foreign Trade

In 2000, dead-burned magnesia exports from the United States declined by about 10% (table 5). Canada, with 85% of the total, was the principal destination. Caustic-calcined magnesia exports, however, increased to nearly four times the 1999 level. Mexico (26%), Japan (19%), Brazil (11%), and the Netherlands (11%) were the main destinations.

U.S. imports of dead-burned magnesia in 2000 increased by 28% from those in 1999 (table 7). China (69%) and Australia (13%) were the principal source countries. One of the reasons for the significant increase in imports was to replace some of the domestically produced material that was lost when National Refractories and Minerals closed its magnesia plant in 1999.

Imports of caustic-calcined magnesia increased by 11% from imports in 1999. China (65%) and Canada (29%) were the primary sources. In spite of the export licensing requirements imposed by the Chinese Government, magnesia exports from

Digitized by Google

China to the United States continued to rise. For 2000, the Chinese export quota for magnesite was 1.6 million metric tons (Mt), and the license fee was about $43 per metric ton. Because of falling magnesite prices, many Chinese producers joined to form two separate export syndicates. The producers expected to be able to control prices and export volumes more easily through these syndicates (Industrial Minerals, 2000f).

Trade data for olivine are not available separately from the U.S. Census Bureau. The Journal of Commerce Port Import/Export Reporting Service (PIERS), however, provides data on material that travels by ship. PIERS data indicate that in 2000 the United States exported 871 metric tons (t) of olivine; Argentina (42%), Venezuela (12%), and Brazil (11%) were the principal destinations. U.S. olivine imports totaled 202,000 t, a 73% increase from imports in 1999. Norway (70%) and Poland (28%) were the major source countries.

World Review

Australia.—SAMAG Ltd., the 80%-owned subsidiary of Pima Mining NL, began trial mining of its magnesite deposit in South Australia. The company plans to mine about 2,000 t of ore for trial leaching tests. The company also selected Port Pirie as the site for its proposed 52,500-t/yr magnesium plant. This site was chosen because of its existing infrastructure (the Pasminco zinc smelter is located at the same site), the rail link between Port Pirie, and the location of the magnesite raw material near Leigh Creek. Initial investment in the plant was expected to begin in 2001, with commercial production scheduled for 2004. The company has licensed The Dow Chemical Co.'s electrolytic technology for magnesium production (Metal Bulletin, 2000). SAMAG also purchased the Myrtle Springs and the Huandot magnesite deposits from Unimin Australia Ltd., which increased the company's total magnesite resources in the Leigh Creek, Northern Territory, area to 579 Mt (Pima Mining NL, November 28, 2000, SAMAG purchases additional magnesite resources, accessed January 8, 2001, at URL http://www.pima.com.au/temp.asp?t=asx28nov00).

In October, Mt. Grace Resources NL began bulk magnesite mining operations at its Batchelor magnesium project. The company planned to mine and stockpile 2,000 t of magnesite to provide sample material for test work. An ore parcel was expected to be sent to Mintek in Johannesburg, South Africa, in January for testing (Mt. Grace Resources NL, October 30, 2000, Mt[.] Grace Resources mines ore at Batchelor, accessed November 8, 2000, at URL http://www.mtgrace.com/releases/oct_30_2000.html). Mt. Grace Resources plans to construct a 50,000-t/yr magnesium plant by 2006.

At the end of June, Unimin acquired Normandy Mining Ltd.'s mining assets, which included all its activities under its Commercial Minerals Ltd. subsidiary. Commercial Minerals operates a magnesite mining operation near Myrtle Springs, South Australia (Industrial Minerals, 2000h).

Canada.—Globex Mining Enterprises Inc. acquired the Deloro magnesite deposit after its previous owner, Royal Oak Mines Inc., filed for bankruptcy. Drilling on the property has delineated a resource of more than 100 Mt of ore, containing more than 50% magnesite, 25% to 30% talc, and 16% quartz. The company was reviewing test results conducted in 1991 and was planning to conduct bulk sampling tests before determining how it would develop the deposit (North American Minerals News, 2000b).

China.—For 2001, the quantity of magnesia available for export was the same as it was in 2000—1.6 Mt. The export license fee, however, decreased by approximately $1 per metric ton to $42 per metric ton (Houssa, 2001).

Greece.—Grecian Magnesite S.A. embarked on an investment program designed to improve processing at its operations in Greece and to internationalize the company. As part of its internationalization strategy, Grecian Magnesite acquired 40% of the Spanish holding company Magna Inversiones S.A., which owns the Spanish magnesite producer Magnesitas Navarras S.A. Grecian Magnesite also plans to add two new mineral processing lines that are intended to increase productivity, reduce production costs, and improve the company's environmental protection efforts. The total cost of the acquisition and the production modifications was estimated to be $7 billion, and part of this investment was expected to be financed through stock offering on the Athens Stock Exchange Market (Grecian Magnesite S.A., June 20, 2000, Investment program of Grecian Magnesite S.A., accessed February 12, 2001, at URL http://www.grecianmagnesite.com/Press/pr20062000.html). As part of Grecian Magnesite's modifications, Bateman Project Holdings Ltd. supplied a new 30-metric-ton-per-hour dense-media separation plant to its mine at Yerakini, which was designed to separate waste rock from magnesite.

India.—Almora Magnesite Ltd. was referred to India's Board of Industrial Finance and Reconstruction for assessment of its finances. As a result, the company was looking for foreign investment to develop its magnesite mines and to upgrade its beneficiation plant. Almora Magnesite produced about 50,000 t/yr of crude magnesite and 20,000 t/yr of dead-burned magnesia at its plant in Uttar Pradesh. Competition from imports of Chinese magnesite and a downturn in the domestic steel industry had put financial pressure on India's magnesite producers. In addition, the dead-burned magnesite produced in India has a high silica content, which makes it unsuitable for production of many higher value refractories such as magnesia-carbon brick (Industrial Minerals, 2000a).

Israel.—Dead Sea Periclase Ltd. announced that it would increase magnesium hydroxide production capacity at its Mishor Rotem plant to 9,000 t/yr, a 3,000-t/yr increase. The first phase of the two-phase expansion was completed in September; the remaining capacity was expected to be completed by early 2001. The company was increasing its capacity because of a successful audit from the country's Food and Drug Administration. The successful audit was expected to increase demand for the company's magnesium hydroxide from the food and pharmaceutical industry (Chemical Week, 2000).

Jordan.— Jordan Magnesia Co. received a $30-million loan from a syndicate of banks, which would allow it to proceed with construction of its planned magnesia plant. The company already had received $28 million from the Islamic Development Bank and the Islamic Portfolio. The total cost of the plant was estimated to be $101 million. Plant commissioning was scheduled for the beginning of 2001, and the annual plant capacity will be 50,000 t of dead-burned magnesia and 10,000 t of specialty magnesium compounds. About 489,000 cubic meters per year of magnesium chloride-rich brine from Arab Potash Co.'s existing solar ponds and 165,000 t/yr of limestone mined from a quarry at nearby Qatrana will supply the plant's feedstock (Fertilizer International, 2000).

Digitized by Google

Russia.—After celebrating a century of mining in September and extracting its 200 millionth metric ton of ore from the Satka magnesite deposits in August, JSC Kombinat Magnezit announced plans to improve its magnesite mining and processing operations. Magnezit operated two open pit mines, one underground mine, and two beneficiation plants with a capacity to produce about 2.5 Mt of magnesia products annually. The company planned to construct a briquetting and processing plant that can use dust from its magnesite beneficiation operation as feed material. The company also acquired the mining rights to the Goluboe magnesite deposit, which has reserves of 6 Mt, including 2 Mt of magnesite containing 45% MgO. Magnezit planned to construct a fused magnesia plant using magnesite from the Goluboe deposit as feed material. Magnezit also planned to prolong the life of its open pit mines by mining more ore from its underground mine (Industrial Minerals, 2000d, e).

Magnitogorsk Iron and Steel Works, one of Russia's largest steel producers, commissioned a new magnesia-dolomite refractories plant in 2000. The first stage of the new operation, with a capacity of 12,000 t/yr, began producing magnesia-carbon bricks to replace refractories previously purchased from Magnezit. The second stage was expected to add 18,000 t/yr of dolomite refractories production to the plant. Total cost of the project was estimated to be $40 million. When the plant is completed, Magnitogorsk will be able to supply about 70% of its refractories needs with material produced in-house (Industrial Minerals, 2000g).

Turkey.—In May, Austria's Styromagnesit Steirische Magnesitindustrie GmbH (Styromag) purchased Comag Continental Mining Industry & Trade Co. Inc. The purchase included Comag's mine and plants in Middle Anatolia, Turkey, with a capacity of 50,000 t/yr of caustic-calcined magnesite, that had been shut since March. Styromag planned to restart the operation in July under the name Calmag. Previously, much of the operation's production had been used for animal feed, but Styromag wanted to concentrate on sales of fused magnesia. The acquisition would also broaden Styromag's product line of caustic-calcined magnesia products—Styromag produced crystalline magnesite at its Austrian operation, and the Calmag operation produced cryptocrystalline magnesite (Industrial Minerals, 2000i).

The Turkish refractories producer Haznedar Ates Tugla Sanayii A.S. planned to begin production in early 2001 at a new refractories operation in Istanbul. The new plant will replace an old 30,000-t/yr operation producing magnesia-carbon and alumina bricks. The new plant, which will produce about 50,000 to 60,000 t/yr of high-density alumina and magnesia bricks, will incorporate some of the old equipment into the new facility. The company hoped to improve product quality. About 75% of the refractories were used locally, and the rest were exported to neighboring countries (Industrial Minerals, 2000c).

Current Research and Technology

Krosaki Harima Corp. developed a new brand of refractory product that was considered to be more environmentally friendly than traditional refractories. In the alumina monolithics that the company produced, it replaced the Cr_2O_3 with MgO. Replacing the Cr_2O_3 with MgO eliminates the generation of hexavalent chromium, which can lead to environmental problems when discarding the refractories (Industrial Minerals, 2000b).

Outlook

Because the primary use of refractory magnesia is in iron and steel production furnaces, economic factors that influence the production of iron and steel will have a direct effect on the consumption of refractory magnesia. According to the International Iron and Steel Institute, the North American steel industry is concerned about higher energy prices and increased levels of imports (International Iron and Steel Institute, October 3, 2000, IISI survey reveals renewed world steel consumption growth, accessed April 16, 2001, at URL http://www.worldsteel.org/trends_indicators/demand.html). If energy costs remain high or increase, it could lead to closure of some North American steel production capacity. This, in turn, could lead to higher levels of imports, which would be required to supply the steel demand. Also, if the U.S. economy becomes stagnant or enters a recession, the total demand for steel is likely to decline as well. A decline in steel demand coupled with closure of U.S. capacity would lead to a significantly reduced demand for refractory magnesia.

Imports of magnesite, mainly from China, are expected to continue to supply much of the U.S. demand for magnesia for refractory applications. If material from North Korea becomes available on the U.S. market, it would probably provide an additional source of low-cost magnesia to U.S. refractories manufacturers at the expense of domestically produced material. Consumption of caustic-calcined magnesia, however, is expected to continue to be strong. Because it has such diverse applications, a decline in one particular industry sector is not as devastating as a drop in steel production is to the refractory magnesia industry. Such environmental applications as wastewater treatment are expected to continue to be the principal growth area for caustic-calcined magnesia.

TABLE 2
U.S. MAGNESIUM COMPOUND PRODUCERS, BY RAW MATERIAL SOURCE, LOCATION, AND PRODUCTION CAPACITY, IN 2000

Raw material source and producing company	Location	Capacity (metric tons of MgO equivalent) 1/	Products
Brucite: Applied Chemical Magnesias Corp.	Van Horn, TX; and Bullhead City, AZ	25,000	Magnesium hydroxide.
Magnesite: Premier Services Inc.	Gabbs, NV	140,000	Caustic-calcined and dead-burned magnesia.
Lake brines:			
IMC Kalium Ogden Corp.	Ogden, UT	105,700	Magnesium chloride and magnesium chloride brines.
Reilly Industries Inc.	Wendover, UT	45,000	Magnesium chloride brines.
Well brines:			
The Dow Chemical Co. 2/	Ludington, MI	214,000	Magnesium hydroxide.
Martin Marietta Magnesia Specialties Inc. 3/	Manistee, MI	297,000	Caustic-calcined and dead-burned magnesia.
Rohm and Haas Co.	do.	10,000	Magnesium carbonate, magnesium hydroxide, and caustic-calcined magnesia.
Seawater:			
Barcroft Co.	Lewes, DE	5,000	Magnesium hydroxide.
Premier Services Inc.	Port St. Joe, FL	50,000	Caustic-calcined magnesia and magnesium hydroxide.
Western Salt Co.	Chula Vista, CA	3,000	Magnesium chloride brines.
Total		894,700	

1/ Data are rounded to no more than three significant digits; may not add to total shown.
2/ Most of Dow's production was shipped to RHI Refractories America Inc. in Ludington, MI, where it was converted to dead-burned magnesia at a 200,000-metric-ton-per-year plant.
3/ In addition to its Michigan plant, Martin Marietta owned a 30,000-metric-ton-per-year magnesium hydroxide plant in Pittsburgh, PA, and a 15,000-metric-ton-per-year magnesium hydroxide plant in Lenoir City, TN, which used imported magnesite as a raw material.

MANGANESE

By Thomas S. Jones

Domestic survey data and tables were prepared by Jesse J. Inestroza, statistical assistant, and the world production tables were prepared by Glenn J. Wallace, international data coordinator.

Manganese (Mn) is essential to iron and steel production by virtue of its sulfur-fixing, deoxidizing, and alloying properties. Steelmaking, including its ironmaking component, has accounted for most domestic manganese demand, presently in the range of 85% to 90% of the total demand. Among a variety of other uses, manganese is a key component of certain widely used aluminum alloys and is used in oxide form in dry cell batteries. The overall level and nature of manganese use in the United States is expected to remain about the same in the near term. No practical technologies exist for replacing manganese with other materials nor for utilizing domestic deposits or other accumulations in order to reduce the complete dependence of the United States on foreign countries for manganese ore.

Domestic consumption of manganese ore, exclusive of the relatively small quantities used at iron and steel plants, increased marginally, and was just slightly less than the average consumption for the prior 4 years. Unit consumption of manganese in steel, as ferroalloys and metal, was 6 kilograms per metric ton (kg/t) of raw steel produced, as estimated from apparent consumption calculations. This level also was about the same as the average for the prior 4 years.

For U.S. foreign trade in manganese materials, volumes generally decreased for exports and increased for imports. On a content basis, the number of manganese units imported increased by about 9%, while the number of units exported declined by about 14%. The volume of receipts reached new record levels for manganese dioxide (third successive year) and silicomanganese.

Prices reversed the trend of 1999 and increased for ore and ferroalloys. The amount of increase was about 7% internationally for metallurgical-grade ore; and, for imported ferroalloys on a year-average basis, 6% for high-carbon ferromanganese, 23% for medium-carbon ferromanganese, and 8% for silicomanganese. In 2000, ferroalloy prices were at their highest in the first half of the year. Sales of manganese materials from the Government's National Defense Stockpile reduced the Government's inventory of manganese by about another 5%, leaving an inventory about 1.5 times annual domestic consumption. The larger disposals were of high-carbon ferromanganese and metallurgical-grade ore.

World production of manganese ore was estimated to have increased about 11% (contained weight) in comparison with that for 1999. (See table 1.) China was assumed to be the largest producer on a gross weight basis; South Africa easily was the largest producer on a contained weight basis. A number of the larger ferroalloy producers revamped their operations, such as those in Brazil, France, and South Africa. In Ukraine, production of ore and ferroalloys increased significantly.

Most data in this report are rounded by the U.S. Geological Survey (USGS) to not more than three significant digits. Table footnotes indicate which statistics have been rounded.

Legislation and Government Programs

Stockpile.—The proposed Annual Materials Plan (AMP) for fiscal year 2001 that the Defense National Stockpile Center (DNSC) of the Defense Logistics Agency issued on October 3 was the same with respect to manganese as in the AMPs that were in effect for fiscal years 1999 and 2000. The AMP for

Manganese in the 20th Century

In the early 1900s, annual domestic apparent consumption of manganese was in the range of 100,000 to 200,000 metric tons. Annual ore consumption was about 100,000 tons, of which approximately 90% was derived from imported ore. World production of ore was in the range of 1 to 2 million metric tons. Domestic ore production, which virtually had ceased by 1970, mostly had been as manganiferous ore such as that coproduced with iron ore. At the close of the century, annual domestic apparent consumption of manganese was about 750,000 tons valued at approximately $400 million. World output of ore was approximately 20 million tons per year.

Manganese demand had been driven mainly by steel production, which typically accounted for 85% to 95% of total manganese demand. The importance of manganese to steel production and the lack of domestic production led to the establishment of a number of Government programs to ensure manganese supply, including buildup of sizable inventories, particularly beginning in the 1950s. The trend in manganese demand in steelmaking was displaced downwards beginning about 1980 because of changes in steelmaking technology.

Domestically, ore was smelted to ferromanganese mainly in blast furnaces until the late 1970s. The last remaining domestic ferromanganese producer used electric furnace production for manganese ferroalloys, a process whose early usage was spurred by World War I. Manganese metal and dioxide were developed as electrolytic products in the 1930s and 1940s. Research by the former U.S. Bureau of Mines contributed importantly to commercialization of electrolytic methods for producing manganese metal and dioxide. Electrolytic manganese dioxide became a key ingredient in household batteries, and the demand for it had the highest growth rate of any manganese commodity product.

Digitized by Google

fiscal year 2001 became effective as of October 1, 2000, the start of the 2001 fiscal year. Under this AMP, the maximum disposal authority for manganese materials was 27,216 metric tons (t) for natural battery-grade ore; 2,732 t for synthetic manganese dioxide; 36,287 t for chemical-grade ore; 226,796 t for metallurgical-grade ore; 45,359 t for the manganese ferro group; and 1,814 t for electrolytic manganese metal.

In its sales program for metal, the DNSC amended as of October 1 its Solicitation of Offers DLA-ELECTROLYTIC MANGANESE METAL-001 so as to make available the same quantity of metal; 1,814 t, as in the AMP. When originally issued on May 1, 1997, the quantity of metal being made available was 1,053 t.

For 2000, disposals of manganese materials announced by the DNSC totaled 5,988 t for natural battery-grade ore; 6,565 t for chemical-grade ore; 37,987 t for stockpile-grade metallurgical-grade ore; 90,719 t for high-carbon ferromanganese; and 146 t for electrolytic metal. All disposals were cash transactions.

Data on physical inventory of manganese materials reported by the DNSC indicated that all net changes in 2000 were decreases and consisted of 5,928 t for natural battery-grade ore, 3,600 t for chemical-grade ore, 52,060 t for stockpile-grade metallurgical-grade ore, 923 t for nonstockpile-grade metallurgical-grade ore, and 32,524 t for high-carbon ferromanganese. The estimated manganese content of manganese inventories being held by the Government at yearend was lowered in 2000 by about another 5%, to somewhat greater than 1.1 million metric tons (Mt). (See table 2.) The total remaining inventory was about 1.5 times current national apparent consumption.

Other.—In August, the Drug Enforcement Administration of the U.S. Department of Justice sustained its 1998 suspensions of three shipments of Chinese potassium permanganate that were to have been transshipped to Colombia through ports in California. These shipments were suspended because of the possibility that they might be diverted for use in the manufacture of cocaine (Drug Enforcement Administration, 2000).

In November, the Agency for Toxic Substances and Disease Registry of the U.S. Department of Health and Human Services announced that six updated final toxicological profiles for priority hazardous substances had become available (Agency for Toxic Substances and Disease Registry, 2000). One of these, Toxicological Profile for Manganese, emphasized the health effects of manganese and related toxicological information (Sciences International, Inc., 2000).

As of December 26, the Employment and Training Administration (ETA) of the U.S. Department of Labor certified that specified current and former workers at the North Plant of Eramet Marietta Inc., Marietta, OH, were eligible to apply for benefits under the Trade Adjustment Assistance (TAA) program administered by ETA. This determination was made after Eramet Marietta had notified the ETA that it had accepted delivery of imported manganese metal in place of its own production (Employment and Training Administration, 2001). Shortly before that, the ETA had determined that these workers were not eligible to apply for such assistance (Employment and Training Administration, 2000). Under the TAA program, workers whose jobs are adversely affected by increased imports can receive various benefits and services designed to help them obtain suitable employment.

Production

Ore and Concentrate.—The only possible mine production of manganese consisted of small amounts of manganiferous material having a natural manganese content of less than 5%. This type of material has been produced in South Carolina for use in coloring brick.

Ferroalloys, Metal, and Synthetic Dioxide.—Production statistics for these materials were not published to avoid disclosing proprietary data. The only plant at which manganese ferroalloys were produced domestically was that of Eramet Marietta at Marietta, OH (table 3). In July, Eramet Marietta announced that by the end of the year it would close its facilities for producing manganese metal. Production of metal was a minor part of that plant's overall production program that included an annual output of about 170,000 t of manganese ferroalloys. Production of manganese-aluminum briquets for use as aluminum hardeners was to continue using manganese not produced at Marietta (Platt's Metals Week, 2000).

Consumption, Uses, and Stocks

Data relating to manganese end use and certain other information have indicated that metallurgical applications account for most domestic manganese consumption, 85% to 90% of which has been for steelmaking. This usage pattern is typical for most industrialized countries (Mining Magazine, 1990). Reported data for U.S. ore consumption in 2000 indicated that unit consumption of manganese in ironmaking, which could not be published to avoid disclosing proprietary data, declined from that for 1999 to become an even smaller comparatively minor component of overall manganese use in steelmaking. Reported data for U.S. consumption of manganese ferroalloys and metal in 2000 are presented in table 4. Data in this table are not directly comparable to those for years prior to 1998, especially for ferromanganese. Also, because of the incompleteness of reporting to the USGS's voluntary consumption survey, the figures in this table are more representative of relative rather than absolute quantities. Combination of the indicated consumption pattern with estimates of apparent consumption suggests that manganese unit consumption in steelmaking in 2000 was about 6 kg/t or about twice that if calculated on the basis of reported consumption. Overall domestic manganese apparent consumption in 2000 was estimated as 774,000 t.

In decreasing order, the most important steel end uses in the United States were given as construction, automotive, machinery, and domestic and commercial equipment (Iron & Steelmaker, 2000).

Ownership of plants for manufacture of manganese sulfide used, for example, in parts made by iron powder metallurgy, were included in the sale of the Pyron Corp. and Pyron Metals Powders, Inc., subsidiaries of Zemex Corp., Toronto, Canada, to Sweden's Höganäs AB. Plants involved in the sale were located in New York, Pennsylvania, and Tennessee (Skillings Mining Review, 2000).

Relatively small quantities of manganese were used for alloying with nonferrous metals, chiefly in the aluminum industry as manganese-aluminum briquets that typically

Digitized by Google

contained either 75% or 85% manganese. The small addition to manganese demand from the U.S. Mint's introduction in 1999 of the so-called Golden Dollar was diminished because of the new coin's lack of popularity (Day, 2001).

In 2000, domestic consumption of manganese ore increased by a marginal amount to 486,000 t, while corresponding yearend stocks increased by about 31% to 226,000 t. Because of the need to avoid disclosing proprietary data, these figures do not include the relatively small quantities associated with ironmaking and cannot be disaggregated into end-use segments.

Comparatively small amounts of manganese were used domestically in animal feed, brick coloring, dry cell batteries, manganese chemicals, and fertilizers. These were among the many nonmetallurgical applications of manganese (Weiss, 1977; Harben, Raleigh, and Harris, 1998). The source of manganese units for these applications was mainly manganese ore. As discussed under Spain in the World Review section of this report, Carus Chemical Co., Peru, IL, the only domestic producer of potassium permanganate, completed its acquisition of the only Spanish maker of that chemical. Remediation of sites such as those of Government facilities that have been contaminated with chlorinated solvents was a growing application for potassium permanganate (Wickramanayake, Gavaskar, and Chen, 2000a, b). In December, TETRA Technologies, Inc., headquartered in The Woodlands, TX, in exiting the micronutrients business, sold all of its U.S. and foreign manganese sulfate assets (TETRA Technologies, 2001, p. 15). TETRA had been producing manganese sulfate at plants at Fairbury, NE, and in Mexico. Sale of the Mexican plant is discussed under Mexico in the World Review section of this report.

Data on domestic consumption of manganese ore, exclusive of that consumed within the steel industry, are collected by means of the Manganese Ore and Products survey. Approximately 15 firms were canvassed that process ore by such methods as grinding and roasting or that consume it in the manufacture of dry cell batteries and manganese ferroalloys, metal, and chemicals. The collective consumption of these firms is believed to constitute all manganese ore consumption in the United States, exclusive of that by the steel industry. Full-year responses, or a basis upon which to estimate the data, were obtained from all these firms for 2000.

In batteries containing manganese, those of the alkaline type in which electrolytic manganese dioxide (EMD) is used continued to expand their share of the market at the expense of those of the carbon-zinc type in which natural battery-grade ore is a component. Market penetration of alkaline batteries in 2000 was 91% for North America, 62% for Europe, 32% for Latin America, and 26% for Asia. New products were aimed at applications requiring a high discharge rate, such as in digital cameras. Battery sales in 2000 were depressed by the abnormally high sales in the last quarter of 1999 that were brought on by anticipation of Y2K problems (MacArthur and Blomgren, 2001, p. 35-37). In military applications, lithium-sulfur dioxide batteries were being replaced mostly by those of the lithium-manganese dioxide type (Advanced Battery Technology, 2000).

In April, the battery products business of Ralston Purina Co. was spun off into Energizer Holdings, Inc., an independent company, that included the Eveready Battery Co., one of the principal domestic battery makers (Haflich, 2000). Ralston Purina and Energizer were headquartered in St. Louis, MO.

Recycling of batteries such as dry cells, a topic of considerable interest in Western Europe, has led to development of a variety of processes for recovering metals or removing them from the environment. A hydrometallurgical process developed in France recovers manganese as the carbonate or sulfate (Ferlay and Weill, 2000).

Prices

For 2000, if the price of manganese in metallurgical-grade ore is set at 1.0, the corresponding price per manganese unit was approximately 2.6 for high-carbon ferromanganese, 4.2 for medium-carbon ferromanganese, 2.5 for silicomanganese, and 7.5 for manganese metal. Compared with the corresponding price factors for 1999, the factor for high-carbon ferromanganese was unchanged, while those for medium-carbon ferromanganese and silicomanganese are somewhat greater. The factors are based on year-average prices for ferroalloys as derived from prices listed in Platt's Metals Week, and for metal as given in Ryan's Notes (North American transaction price). Year-average prices increased for metallurgical-grade ore and all main categories of manganese ferroalloys.

Manganese Ore.—The average price, on the basis of cost, insurance, and freight (c.i.f.) U.S. ports, of metallurgical-grade ore containing 48% manganese was assessed at $2.39 per metric ton unit. It is recognized that prices were somewhat above or below this value, depending on ore quality, time of year, and nature of the transaction. The price of a metric ton of ore is obtained by multiplying the metric ton unit price by the percentage manganese content of the ore; that is, by 48 when the manganese content is 48%. The ore market consisted of a number of submarkets because of differences between ores according to such various end uses as ferroalloy production, blast furnace ironmaking, and manufacture of manganese chemicals.

Because the metric ton unit is 1% of a metric ton (i.e., 10 kilograms of contained manganese), the price of manganese in ore in 2000 and 1999 can be expressed as 23.9 and 22.6 cents per kilogram, respectively. These values indicate an increase of about 6% in U.S. c.i.f. price or somewhat less than the increase in free-on-board (f.o.b.) price in international markets.

The international benchmark price for metallurgical-grade ore ended a 3-year decline, increasing by about 7% in 2000, or by about the same percentage as for the decrease in 1999. Price negotiations between Japanese consumers, with Nippon Steel Corp. playing a leading role, and their major suppliers were not concluded until late May, or about 2 months after the April 1 beginning of the Japanese fiscal year. On an f.o.b. basis per metric ton unit for delivery during the annual contract year, the prices agreed to were $2.03 for ore from the Groote Eylandt Mine in Australia and $1.94 for ore from the Wessels Mine in South Africa. These prices were negotiated by South Africa's Samancor Ltd., a subsidiary of the United Kingdom's Billiton plc. Samancor had assumed control of both mines late in 1998.

Manganese Ferroalloys.—For high-carbon and medium-carbon ferromanganese, the pattern of price changes was

Digitized by Google

similar, in a general way to that for the change in domestic raw steel production rate—an increase in the first part of the year to a plateau, followed by a decline thereafter. The silicomanganese price was nearly constant through June, after which it declined to a bottom in October that was followed by a modest recovery in November through December. These trends and the price information that follows pertain to quotations for U.S. imports because public information on current prices for domestic product was not available. English units were the basis for price quotes in the United States.

For ferromanganese, the price range for the high-carbon grade containing 78% manganese, per long ton of alloy f.o.b. Pittsburgh or Chicago warehouse, began the year unchanged at $450 to $470 and ended the year at $475 to $490, for a net overall increase of 5%. For the year, the average for the middle of the price range was $482.50, which was about 6% greater than that of 1999. The range for the plateau-like high that was reached as of mid-June was about $500 to $525. The price range for medium-carbon ferromanganese with a manganese content of 80% to 85% and a nominal carbon content of 1.5%, per pound of manganese f.o.b. warehouse, was an unchanged 35 to 38 cents at the beginning of the year and 42 to 45 cents at the end of the year, for a net overall increase of about 19%. The middle of the price range averaged 46 cents for the year, for an increase of 23% over that of 1999. The price range of medium-carbon ferromanganese rose sharply in April to a 3-month long plateau of 50 to 54 cents. During the first part of the year, trade journals spoke of a shortness in ferromanganese supply.

For imported silicomanganese with 2% carbon, the price range, per pound of alloy, f.o.b. Pittsburgh or Chicago warehouse, started the year at 24.5 to 26 cents, or slightly higher than that at the end of 1999, and ended the year at 21 to 22 cents, for a net decrease of 15%. Even so, an average for the year for the middle of the price range of about 23.8 cents was about 8% greater than that of 1999. At the bottom in October, the price range was 19.5 to 20.5 cents.

Manganese Metal.—Trade journals listed the same producer prices that they have been listing since about the beginning of 1996; for bulk shipments of domestic material, per pound f.o.b. shipping point, American Metal Market listed a range of $1.15 to $1.17, and Platt's Metals Week and Ryan's Notes listed $1.15. Platt's discontinued its listing as of its October 2 issue. For its listing of North American transaction price, Ryan's Notes indicated an overall decrease during the year that approached 9%. For this listing, the price range was more or less steady at 78 to 84 cents, January through November, but in December dropped to 72 to 77 cents. The year-average price of about 81 cents for this listing was about 30% below producer list price and about 5% less than that for 1999.

Foreign Trade

In comparison with those of 1999, trade volumes for most categories of manganese materials, in terms of manganese units contained, decreased for exports and increased for imports. (See tables 5 and 6.) Overall, the year-to-year comparisons were -14% for exports and +9% for imports. Also on the basis of content, the ratio of imports of ferroalloy plus metal divided by imports of ore plus dioxide tentatively increased, from 1.86:1 in 1999 to 2.0:1. In the absence of domestic mine production, U.S. net import reliance as a percent of apparent consumption was 100% for manganese, the same as it has been for years.

Within exports, the number of manganese units and the quantity of metal were the least since at least prior to 1983. Exports of ore reportedly were more than twice as great as in 1999. The data remained in question for 4,000 t or more of ore, particularly the large quantity reported as having been exported to the United Kingdom. Exports of manganese ferroalloys and metal all declined; those of total ferromanganese and silicomanganese were the least since 1990. Percentage declines from 1999 ranged from 31% for total ferromanganese to as much as 50% for silicomanganese. Most of the decline in ferromanganese exports was in the subcategory of carbon content greater than 2%. For this category, exports decreased by 49% and share of total ferromanganese exports declined to 43%. Exports of ferromanganese containing more than 2% carbon were 3,450 t and those containing less than 2% carbon were 4,500 t.

Reexports of ore, ferromanganese, silicomanganese, and metal were, in tons, 9,010; 10,600; 2,270; and 246; respectively. Except for metal, all or nearly all of the reexports went to Canada. Other main destinations of reexports of metal were the Republic of Korea, the Netherlands, and Mexico.

Among imports, overall average manganese contents were 78.8% for ferromanganese and tentatively 52.8% for ore. The average manganese content for ferromanganese was the greatest since the same level was attained in 1994. Average contents for ore were abnormally high (55% for ore with greater than 47% manganese). Averages were in question where ore was involved, however, as well as the ore data in general. Questions about obvious discrepancies in a significant portion of the data for Gabon were unresolved at the time this report was prepared. The ore data presented in table 5 indicate that overall imports decreased by 6% and that Gabon's share of receipts rose to 84%.

The import volume for total ferromanganese was virtually the same as in 1999. The most significant year-to-year change was for low-carbon ferromanganese, for which imports increased by 27%. The validity of the data for Brazil in this subcategory was in question, as it seemed likely that the more than 6,000 t reported as low-carbon ferromanganese was actually medium-carbon ferromanganese. If so, the quantity of medium-carbon ferromanganese imported would be a record high. Comparing leading supplying countries of medium-carbon ferromanganese with those in 1999, import volumes increased for China, Japan, and Norway, and decreased for France; for high-carbon ferromanganese, quantities increased for Australia and decreased for France. Declines in these subcategories were especially notable for France, from which imports of high-carbon ferromanganese fell by nearly one-half.

For silicomanganese, an import volume 26% greater than for 1999 was easily a new record. Record amounts were received from India and Kazakhstan, for which the amounts received were 5.6 and 2.4 times as great, respectively, as for 1999. For manganese metal overall, import volume was 5% greater than for 1999. For the unwrought subcategory, increases in shipments from China, Germany (especially), and the United Kingdom contributed to a 17% increase. Imports in the "Other" subcategory fell by two-thirds. Reported imports of spiegeleisen (pig iron containing about 20% manganese)

Digitized by Google

declined to 270 t, all of which was from South Africa at high unit value.

Among imports of manganese chemicals, those of manganese dioxide increased for the second successive year by about one-fourth to set a new record for volume. Amounts received from Australia, Ireland, and South Africa set new records also, increasing by 14% to 19%. After Australia, South Africa continued to lead Ireland as the source of the largest amount. Unit values indicated that virtually all dioxide imports were synthetic material. Data for imports under the classification of "sulfates, other," suggested that imports of manganese sulfate may have decreased by 6%, as the volume of imports of material in that class decreased by 15% for China and increased only marginally for Mexico. Receipts from China were 13,100 t at a value of $4.8 million and those from Mexico 19,000 t at a value of $9.5 million.

Antidumping duties on EMD, manganese metal, and silicomanganese were the subject of investigations by Government trade agencies. For EMD, in May, the U.S. International Trade Commission determined in its full 5-year review that revocation of antidumping duty orders on EMD from Greece and Japan would be unlikely to cause material injury to a domestic industry in the reasonably foreseeable future (U.S. International Trade Commission, 2000a, b). Accordingly, the International Trade Administration (ITA) of the U.S. Department of Commerce revoked these antidumping duty orders effective January 1, 2000. In so doing, the ITA said it would complete pending administrative reviews of these orders and would conduct reviews of EMD imported prior to January 1, if appropriately requested (International Trade Administration, 2000e).

In reviews for EMD subsequently completed, for that from Greece for the period of review (POR) of April 1, 1998, through March 31, 1999, the ITA in November found a margin of 0.00% for Tosoh Hellas A.I.C.; no "all-others" rate was specified (International Trade Administration, 2000a). For that from Japan for the same POR, the ITA in September found a margin of 0.00% for Tosoh Corp. and also did not specify an "all-others" rate (International Trade Administration, 2000b).

For manganese metal from China, for the POR of February 1, 1998, through January 31, 1999, the ITA found a margin of 36.49% for China Metallurgical Import & Export Hunan Corp./Hunan Nonferrous Metals Import & Export Associated Corp. and an "all-others" margin of 143.32%, which also was assigned to China Hunan International Economic Development (Group) Corp. (International Trade Administration, 2000d).

For silicomanganese, the ITA found in its expedited 5-year ("sunset") review of the antidumping duty orders that applied to Brazil and China that revocation of the antidumping orders likely would lead to dumping. For Brazil, the corresponding weighted-average margins were 64.93% for Companhia Paulista de Ferro-Ligas and Sibra Electro-Siderurgia Brasileria S.A. and 17.6% for all others. For China, the margin was 150% for all manufacturers, producers, and exporters (International Trade Administration, 2000f). Also for silicomanganese from China, for the POR of December 1, 1997, through November 30, 1998, the ITA found margins of 126.22% for Guangxi Bayi Ferroalloy Works, 182.97% for Sichuan Emei Ferroalloy Import and Export Co., Ltd., and 150% for all others not specified (International Trade Administration, 2000g).

For silicomanganese from Ukraine, the ITA found in its full sunset review that termination of the suspended antidumping investigation likely would lead to dumping at a country-wide margin of 163% (International Trade Administration, 2000c).

The Generalized System of Preferences (GSP) Program was modified as of December 21 so as to grant duty-free status to certain products from sub-Saharan African countries. High-carbon ferromanganese was among the products to which this form of GSP treatment was extended (Clinton, 2000). Electrolytic manganese metal also had been a candidate for GSP treatment, but it was not included (Ryan's Notes, 2000).

World Review[1]

Leading producer countries among a relatively concentrated production of manganese ore were Australia, Brazil, China, Gabon, India, South Africa, and Ukraine. (See table 7.) Leading producer countries among a more widely distributed production of manganese ferroalloys were China, France, India, Japan, Norway, South Africa, and Ukraine. (See table 8.)

Australia.—Ore production was 15% less for Australia as a whole. Production in Western Australia by Consolidated Minerals Ltd. in the Woodie Woodie area of the Pilbara Manganese Province was nearly twice that for 1999. This did not compensate, however, for a drop in production of about one-fourth at Billiton plc's much larger operations at Groote Eylandt in the Northern Territory; the production level there was the lowest since 1992. Mining by Consolidated Minerals was adversely affected by heavy rains in the first part of the year, but the company still showed a profit for the fiscal year that ended June 30.

Expansion of EMD capabilities was underway on both sides of the continent. Delta EMD Australia Pty. Ltd. raised the annual capacity of its plant at Newcastle, New South Wales, from 23,000 to 25,000 t. In Western Australia, HiTec Energy NL further changed the direction of its program by raising its target capacity for EMD to 40,000 metric tons per year (t/yr) and reducing manganese sulfate to byproduct status, with no target capacity. Encouraging results for EMD produced for HiTec on a pilot plant basis under the technical direction of South Africa's Mintek research organization were to be followed up by operation of a demonstration plant to be set up in the first part of 2001 at Murdoch University in Perth.

Brazil.—Ore production by Cia. Vale do Rio Doce (CVRD) rebounded to increase overall by about 32%. For the Azul Mine in the Carajás region and the Urucum Mine in Mato Grosso do Sul State, output in tons and percentage change in parentheses from 2000 were 1,219,000 (+34%) and 308,000 (+22%), respectively.

Late in the year, CVRD made the decision to combine all its manganese interests into a single company, as opposed to other alternatives such as selling or partnering some or all of its mines and ferroalloy plants. Besides Brazilian operations, the

[1]In a number of instances, discussions of the more-significant developments during 2000 for specific countries were based on news items in trade journals, such as American Metal Market, Metal Bulletin, Platt's Metals Week, Ryan's Notes, and TEX Report. These items have not been acknowledged individually because the information they conveyed often was aggregated, possibly with that from other sources.

Digitized by Google

new company would include the wholly owned ferroalloy plant at Dunkirk, France, whose name was changed as mentioned under France. Among its manganese ferroalloy plants in Brazil, the decision was made not to reopen that at Jeceaba in Minas Gerais State. The Corumbá plant in Mato Grosso do Sul State was reopened and was being upgraded. Output was being raised toward full capacity at Eletrosiderúrgica Brasileira S.A. in Bahia State and, in Minas Gerais State, at Barbacena, Ouro Preto, and Santa Ria. These efforts were projected to give a total production for the year of 240,000 t of manganese ferroalloys.

Shortly after midyear, the United Kingdom's Billiton acquired a 2.1% indirect shareholding in CVRD.

China.—Imports of manganese ore increased by 13% to 1.21 Mt. This ended a downward trend for imports during the preceding 3 years. A significant factor in the increase for 2000 was further growth in receipts from Ghana. Factors contributing to increased shipments from Ghana to China included suitability of Ghanian carbonate ore for production of silicomanganese, substitution for China's own low-grade ore, and use as an alternate to high-grade ore from other producers in the Western World.

In an effort to proceed with its program for rationalizing the domestic ferroalloy industry, the central government instructed local governments to end their financial support of a number of small- and medium-sized ferroalloy plants. How well this request was implemented was uncertain.

An agreement was worked out in the first part of the year with the Republic of Korea that liberalized restrictive measures imposed by the Republic of Korea in late 1998 against China's exporting of silicomanganese to the Republic of Korea (see Korea, Republic of).

France.—One of the high-carbon ferromanganese blast furnaces at the coastal Boulogne-sur-Mer plant of Société du Ferromanganèse de Paris-Outreau (SFPO), an Eramet subsidiary, was shut down during most of the second half of the year. This was done so that this furnace could be refurbished so as to be able to accept sintered ore produced in Gabon from manganese ore from Eramet's Moanda Mine. Also, a dry filtration system for improving environmental control was installed. The shutdown removed about 50,000 t of ferromanganese from the market and kept SFPO's output at about the 300,000 t level.

The name of CVRD's (Brazil) manganese ferroalloy plant, which also is on the coast nearby at Dunkirk, was changed at midyear to Rio Doce Manganese Europe (RDME) from Société Européenne d'Alliages pour la Sidérurgie (SEAS). This plant was producing high-carbon ferromanganese at a rate of about 140,000 t/yr, and also manganese sinter.

Gabon.—At yearend, Compagnie Minière de l'Ogooué S.A. (Comilog) inaugurated a sinter plant with a capacity of 600,000 t/yr along with associated facilities for beneficiating ore from the Moanda Mine. By this means, low-grade ore with a manganese content of 40% was to be upgraded to a sinter with a manganese content of 56% or more. Also, the sinter would effectively replace a portion of the mine's output of lump ore and reduce the quantity of crude ore needing to be extracted. Once the sinter plant's full capacity is reached, three-fourths of its output was to be shipped to SFPO in France for smelting and the balance sold externally.

Ghana.—Overall sales of ore produced at the Nsuta Mine of Ghana Manganese Co. rose by 40%. A significant portion of shipments were to China, particularly of carbonate ore; shipments to China were reported to have been in the range of 200,000 to 300,000 t.

Japan.—Overall imports of metallurgical-grade manganese ore that were only slightly less than those for 1999 gave the same rounded total of 1.02 Mt. The majority of imports were ore containing more than 39% manganese, imports of which decreased about 3% to 927,000 t, of which 94% was from the usual two sources, South Africa (546,000 t) and Australia (325,000 t). Imports of ore containing no more than 39% manganese increased 36%, to 90,900 t, of which virtually all was from South Africa (46,800 t) and India (44,000 t). Imports of ferruginous manganese ore again decreased, by about 38% to 128,000 t; Ghana (45%) displaced India (26%) as the largest supplier, followed by South Africa (19%) and Gabon (8%).

Overall production of manganese ferroalloys increased about 7%. Production of high-carbon ferromanganese and silicomanganese were up by about 13% and 3%, respectively, while that of low-carbon ferromanganese fell by about 11% to become the least since 1992.

Overall imports of manganese ferroalloys decreased about 7%, to 293,000 t. Those of high-carbon ferromanganese dropped again (53,500 t, -33%), those of medium- plus low-carbon ferromanganese rose again (16,200 t, +58%), and those of silicomanganese decreased about 2%, to 224,000 t. South Africa still led China as a source of ferromanganese overall for Japan; of these two countries, China supplied Japan with more high-carbon ferromanganese, while South Africa supplied about 10 times as much medium- plus low-carbon ferromanganese. Shipments of silicomanganese from China to Japan advanced about 16% to 180,000 t.

Exports of manganese ferroalloys more than doubled overall to 44,200 t. Exports of high-carbon ferromanganese increased almost 20 times, to 10,600 t, over 90% of which went to Taiwan. Exports of refined ferromanganese rose 78% to 33,600 t, of which 9,340 t went to the United States, 7,860 t to Taiwan, and 6,440 t to the Republic of Korea.

The year-to-year changes in trade patterns for manganese ferroalloys especially reflected production arrangements made within the past few years between Japanese and South African producers. In a further alignment, Japan's Nippon Denko Co. Ltd. and South Africa's Samancor Ltd. entered into an arrangement commencing April 2000 under which Nippon Denko was to produce high-carbon ferromanganese in place of that which Samancor had been shipping to Japanese customers, and Samancor was to increase its supply of manganese ore to Nippon Denko. The agreement, which included a technology exchange, would increase Nippon Denko's production of high-carbon ferromanganese at its Tokushima plant by about 50,000 t/yr above the 2000 level of about 130,000 t/yr. The agreement also would increase the quantity of Samancor manganese ore being taken by Nippon Denko from about 125,000 t/yr to 200,000 t/yr.

Production of manganese dioxide again rose, by 9%, to 63,400 t, the greatest since that for the record year of 1988. Exports of manganese dioxide declined, however, by 14% to 27,700 t.

Imports of unwrought manganese metal, including scrap, increased about 8%, to 43,300 t; China (77%), South Africa

Digitized by Google

(20%), and the United States (3%) continued as the sources for practically all metal imports.

Kazakhstan.—The manganese deposits of central Kazakhstan and their commercial prospects were reviewed by Takenov and others (2000). Ores from the Ushkatyn III deposit were said to be especially suitable for production of high-carbon ferromanganese, and smelting trials of these ores were discussed.

Disagreement that extended back to 1997 over ownership of and marketing of products from a number of mines and smelters in Kazakhstan was finally resolved in February. Trans-World Group (TWG) of the United Kingdom and the Shodiyev Group reached a settlement under which TWG would be paid for its shares in the assets in dispute, and the Shodiyev Group would assume the managing and product marketing of these assets. The Shodiyev Group was headed by Kazakhstani nationals. The Aksu ferroalloy plant located near Pavlodar was among assets included in the settlement. Manganese ferroalloys are produced at the Aksu plant, which is a part of Kazkhrom, the national chrome corporation. The Tur manganese deposit, to the southwest and also in central Kazakhstan, was being developed as a manganese ore source for the Aksu plant.

Late in the year, a rebuilt furnace was started up for production of manganese ferroalloys at the Temirtau Chemicals and Metallurgical Plant near and to the northwest of Karaganda. The output of this plant, which could be as much as 50,000 t/yr of ferromanganese and silicomanganese combined, was to be shipped a short distance to the Ispat Karmet steel works (Interfax Mining & Metals Report, 2000c). Mining licenses for local ore sources for the Temirtau plant, however, became the subject of a dispute (Interfax Mining & Metals Report, 2000b).

Korea, Republic of.—In mid-March, the Government relaxed measures it took in September 1998 to restrict the importing of Chinese silicomanganese. Under the new measures, effective as of the April-June quarter, silicomanganese could be imported from China without an antidumping duty provided that the quantity per quarter did not exceed 20,000 t, and the price must not be below a floor price set by the Government of the Republic of Korea.

Mexico.—Overall output of ore products by Cía. Minera Autlán decreased by 9%; 2000 quantities in metric tons and, in parentheses, percentage changes from 1999 were manganese carbonates sold, 42,000 (-35%); oxide nodules, 355,000 (-6%); and manganese dioxide, manganous oxide, and other oxides, 21,000 (+31%). Production of nodules was affected when the natural gas-fired kiln being used to nodulize carbonate ore from the mine in Hidalgo State was shut down for December because of the high price of natural gas. Overall production of manganese ferroalloys increased; however, by 6,000 t to a new record total of 199,000 t. A 44% rise in production of high-carbon ferromanganese more than offset decreases of 7% and 5% for refined ferromanganese and silicomanganese, respectively.

In December, TETRA Technologies, Inc., The Woodlands, TX, sold the operations of Industrias Sulfamex, S.A. de C.V., a producer of manganese sulfate and manganous oxide, to Comilog U.S., a holding company subsidiary of Eramet. Capacities of Sulfamex' Tampico plant were 27,000 t/yr for the sulfate and 24,000 t/yr for the oxide (Chemetals Inc., 2000).

Norway.—During the last quarter of the year, Tinfos Jernverk A/S commissioned a new furnace at its Kvinesdal plant near the southern tip of Norway. Addition of this third furnace raised capacity of the plant for silicomanganese to approximately 180,000 t/yr, or by about 60,000 t/yr.

Russia.—The West Siberian Metallurgical Combine (ZSMK) at Novokuznetsk in southwestern Siberia commissioned mining and processing facilities from which as much as 100,000 t of low-grade concentrate (18% to 25% manganese content) would be produced from the Durnovskoye deposit. By this means, the need to import ores from Kazakhstan and Ukraine for ZSMK's steel production would be reduced (Interfax Mining & Metals Report, 2000e). The Durnovskoye deposit is near Leninsk-Kuznetsky, slightly north of Novokuznetsk.

Blast furnace production of ferromanganese decreased at the Kosogorsky metallurgical plant at Tula south of Moscow because only one furnace was being used to produce ferromanganese in at least the first part of the year (Interfax Mining & Metals Report, 2000d). Late in the year, legal troubles involving payments to Trans Commodities Inc. caused the Kosogorsky plant to be placed under court supervision (Interfax Mining & Metals Report, 2000a).

South Africa.—According to preliminary data, production of metallurgical-grade ore and total ore increased by about one-sixth to the highest levels since 1990. All but 0.6% of total production was metallurgical-grade ore, the rest being chemical-grade ore, production of which has been declining since 1996. Within the production of metallurgical-grade ore, the proportions accounted for by ore containing 30% to 40% manganese and by ore containing more than 48% manganese decreased slightly to about 29% and 57% of the total, respectively. Production of ore containing 45% to 48% manganese rose 26-fold to the highest level since 1990, and accounted for about 8% of production of metallurgical-grade ore.

Toward yearend, Samancor reconfigured manganese ferroalloy operations at its Metalloys plant at Meyerton near Johannesburg. Seven smaller furnaces that had been producing silicomanganese were shut down, possibly permanently. All but about 40,000 t/yr of the productive capacity of these furnaces potentially was to be made up once maintenance was completed on one of the three large furnaces at the plant. This furnace had been used to produce high-carbon ferromanganese but could be used to produce silicomanganese. Even with such a change, productive capacity for high-carbon ferromanganese was expected to be maintained using only the two remaining large furnaces owing to achievement of higher operational efficiencies.

In another development affecting Samancor's ferroalloys output, Samancor and Japan's Nippon Denko worked out a long-term agreement that would favor Samancor's shipping of ore rather than high-carbon ferromanganese to Japan (see Japan).

In June, Delta (E.M.D.) (Pty.) Ltd. announced that by the second half of 2001 it would expand the annual capacity of its EMD plant at Nelspruit, Mpumulanga Province, by 11,000 t, or by 50%. The expansion project included provision for infrastructure sufficient for an ultimate capacity of 50,000 t, and also installation of a kiln in Northern Cape Province for Delta EMD's own production of reduced ore feed. Feed from

Digitized by Google

the kiln would supplement that currently being obtained from the adjacent plant of Manganese Metal Co. (Pty) Ltd. in Nelspruit (Industrial Minerals, 2000).

Spain.—In July, the permanganate business of Industrial Quimica del Nalón (IQN) was acquired by Carus Chemical Co., headquartered at Peru, IL, in the United States and one of the world's few producers of potassium permanganate. The acquisition was made a subsidiary of Carus named Carus Nalon S.L., which included the former IQN plant at Trubia on the north coast near Oviedo. In recent years, this plant had been the only site in the European Economic Community at which potassium permanganate was being produced (Carus Chemical Co., 2000).

Ukraine.—Output of manganese concentrates rose 38%, as production was up 30% to 1.82 Mt at the Ordzhonikidze complex in the western part of the Nikopol' Basin and 58% to 917,000 t at the Marganets complex in the eastern part of the basin (Interfax Mining & Metals Report, 2001b). Of a total production that was the greatest since 1997, about two-thirds was by the Ordzhonikidze complex and one-third by the Marganets complex.

A review of manganese mining and beneficiation in the Nikopol' basin gave the makeup of the Ordzhonikidze complex as eight quarries, three beneficiation plants, and one agglomeration plant. Practical annual capacities of these facilities were stated to be, in Mt per year, 7.1 for extraction of crude ore, 2.28 for production of manganese concentrates, and 0.4 for production of agglomerate. Makeup of the Marganets complex was given as five underground mines, two quarries, two beneficiation plants, and a facility for production of manganese sulfate in solid or solution form. Efforts were underway to deal with beneficiation wastes that consisted of more than 100 Mt with a manganese content of 12.2% at the Ordzhonikidze complex and 120 Mt with a manganese content of from 10% to 18% at the Marganets complex (Postolovskiy, Kravchenko, and Prokopenko, 2000).

Higher outputs at electric furnace plants contributed to an increased production of manganese ferroalloys. Production was up more than 50% at the Nikopol' plant and modestly at the Zaporozh'ye plant (Interfax Mining & Metals Report, 2001a, c). Limited quantities of ferroalloys having a reduced phosphorus content were produced at the Nikopol' plant. At the Kramatorsk Works north of Donetsk in eastern Ukraine, addition of fluxed sinter to the charge was found to improve blast furnace production of ferromanganese (Mishchenko and others, 2000). Also at this works, trials of blast furnace production of silicomanganese showed this unconventional way of making this ferroalloy to be inefficient.

Current Research and Technology

Among many items in the current literature that reported on various aspects of manganese and the topics addressed were the following:

Geology.—Model of sedimentation of banded iron formation and associated iron and manganese ores, with particular reference to South Africa (Klemm, 2000), and a review of manganese in seawater and marine deposits (Glasby, 2000).

Ore Leaching and Reduction.—Leaching of Indian manganese ore (about 32% Mn) with aqueous sulfur dioxide (Naik, Sukla, and Das, 2000), simultaneous leaching of zinc sulfide and manganese dioxide using iron-oxidizing bacteria (Kai and others, 2000), and reduction of manganese ore (Australian and South African samples) with carbon monoxide, in reference to manganese ferroalloy production (Berg and Olsen, 2000).

Electrochemistry of Manganese Oxides.—Summary of presentations made at a special meeting of the International Battery Materials Association on manganese oxides in batteries (Blomgren, 2000; MacArthur and Blomgren, 2001, p. 76-79), review of manganese dioxide electrochemistry (Donne, 2000), and comparison of EMD versus chemical and natural manganese dioxides as cathode material in alkaline batteries (Bowden, Sirotina, and Hackney, 2000).

Lithium-Manganese Oxides.—Intensive research continued to be directed on their use in rechargeable lithium-ion batteries; review of forms of oxides by Whittingham and Zavalij (2000), characterization of commercial powders (Huang and others, 2000), chromium substitution into layered oxides (Hwang, Park, and Choy, 2000), and development of a hydrothermal method for preparing a manganese oxide from a lithium manganese oxide (Tang and others, 2000).

Uses of Manganese Oxides.—Molecular sieves and their potential applications (Suib, 2000), manganese-molybdenum oxides as anodes for electrolysis of seawater (Fujimura and others, 2000), and thin film studies of manganese dioxide as a potential ultracapacitor material (Pang, Anderson, and Chapman, 2000).

Biology.—Review of availability of manganese to biological systems and its effect on them (Sigel and Sigel, 2000).

Environment and Toxicology.—Study of industrial hygiene at a domestic alkaline battery plant (Hanley and Lenhart, 2000) and at manganese ferroalloy plants in Italy (Apostoli, Lucchini, and Alessio, 2000) and Norway (Gunst and others, 2000).

Water Systems.—Control of manganese content in well water supply by using potassium permanganate (Fulton and Ferrand, 2000), and effect of biomineralized manganese on corrosion of steel (Olesen, Nielsen, and Lewandowski, 2000).

Outlook

The trend of domestic and global demand for manganese will continue to follow closely that of steel production. Although growth rates for some nonmetallurgical components of manganese demand, especially batteries, may be higher than for steel production, this situation will have only a minor effect on overall manganese demand.

From 1988 to 2000, U.S. apparent consumption of manganese has been within about plus or minus 14% of 680,000 t of contained manganese. This largely has been a consequence of a reasonably comparable degree of variation in domestic steel production. During this period, manganese apparent consumption (see table 1) has tended to increase at about the same rate as raw steel production. Manganese apparent consumption may not have tracked steel production precisely because of the influence of unmeasured changes in stocks of manganese materials, such as those of importers. The effect of this may have outweighed changes in demand by steelmakers and may explain why for some years calculated apparent consumption showed positive or negative deviations from that which could be estimated on the basis of steel

Digitized by Google

production.

Data of the American Iron and Steel Institute indicated that overall domestic raw steel production increased in 2000 by about 4%, which makes it likely that domestic manganese consumption increased by about the same extent. The trend line for manganese apparent consumption suggests that consumption will reach 800,000 t within 5 years. This is contingent upon U.S. raw steel production maintaining the past trend of an annual growth rate close to 1.4%, and no significant change in manganese unit consumption by U.S. steelmakers. The outlook for steel production to increase at a rate similar to that for the past two decades was not favorable, at least in the immediate future, in view of a downturn in the domestic economy that was continuing into 2001. Also, the October 2000 midterm forecast for 2000 through 2005 of the International Iron and Steel Institute (IISI) suggested a slow recovery, as the compound annual growth rate projected for steel consumption in the North American Free Trade Agreement countries was only 0.9% (Ian Christmas, Secretary General, International Iron and Steel Institute, October 3, 2000, IISI survey reveals renewed world steel consumption growth, accessed June 1, 2001, at URL http://www.worldsteel.org/trends_indicators/demand.html). For the automotive industry, demand for steel was seen as remaining important but in decline overall, whereas cast iron seemed increasingly likely to be replaced by aluminum (Wrigley, 2000). The majority of U.S. demand for manganese units will be met by imports.

Globally, growth trends for manganese demand similarly are linked strongly with steel production, which rose to a record level in 2000. In its October 2000 midterm steel consumption forecast for 2000 through 2005, the IISI projected an annual growth rate of 2% for the world overall. Higher growth rates were projected for Asian countries other than Japan; for China, the rate projected was 3.8%. One of the major companies in the world's manganese industry was not optimistic about growth in the midterm, foreseeing a growth of only 1.9% in the amount of steel produced worldwide during 2000 through 2005 (Bacardats, 2000). This company also foresaw that growth in global manganese demand would be held down by decreases in manganese unit consumption, particularly in countries such as China. Consumption was expected to trend downward for high-carbon ferromanganese and upward for silicomanganese and refined manganese ferroalloys. Buying patterns of U.S. steel mills were reported to be in line with this outlook (Ryan's Notes, 2001). Like the steel industry, the manganese industry continued to be challenged by overcapacity for mining and smelting.

TABLE 1
SALIENT MANGANESE STATISTICS 1/

(Thousand metric tons, gross weight)

	1996	1997	1998	1999	2000
United States:					
Manganese ore (35% or more Mn):					
Exports	32	84	8	4	10
Imports for consumption	478	355	332	460	430
Consumption 2/	478	510	499	479	486
Stocks, December 31, consumers 2/	319	241	163	172	226
Ferromanganese:					
Exports	10	12	14	12	8
Imports for consumption	374	304	339	312	312
Consumption 3/	326	337	290	281	300
Stocks, December 31, consumers and producers	27	21	26	40	31
Consumption, apparent, manganese 4/	776	643	776	719	774
Ore price, dollars per metric ton unit, c.i.f. U.S. ports	3	2	2	2	2
World, production of manganese ore	24,300	21,900	20,100 r/	17,900 r/	20,200 e/

e/ Estimated. r/ Revised.

1/ Data are rounded to no more than three significant digits.

2/ Exclusive of iron and steel plants.

3/ Data for 1998 and later not directly comparable to that for prior years.

4/ Thousand metric tons, manganese content. Based on estimates of average content for all significant components except imports, for which content is reported.

TABLE 2
U.S. GOVERNMENT DISPOSAL AUTHORITIES AND INVENTORIES FOR MANGANESE MATERIALS AS OF YEAREND 2000 1/

(Metric tons, gross weight)

		Physical inventory				
		Uncommitted			Sold,	
Material	Disposal authority	Stockpile grade	Nonstockpile grade	Total	pending shipment	Grand total
Natural battery ore	106,000	89,500	16,800	106,000	874	107,000
Synthetic manganese dioxide	2,730	2,730	--	2,730	--	2,730
Chemical ore	137,000	137,000	--	137,000	4,010	141,000
Metallurgical ore	878,000	547,000	331,000	878,000	103,000	982,000
High-carbon ferromanganese	582,000	772,000	--	772,000	78,900	851,000
Electrolytic metal	5,640	5,640	--	5,640	146	5,790

-- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

Source: Defense National Stockpile Center.

TABLE 3
DOMESTIC PRODUCERS OF MANGANESE PRODUCTS IN 2000

		Products 1/				
Company	Plant location	FeMn	SiMn	Mn	MnO_2	Type of process
Chemetals Inc. 2/	Baltimore, MD				X	Chemical.
Do.	New Johnsonville, TN				X	Electrolytic.
Eramet Marietta Inc.	Marietta, OH	X	X	X		Electric furnace and electrolytic.
Kerr-McGee Chemical LLC	Hamilton, MS			X		Electrolytic.
Do.	Henderson, NV				X	Do.
Ralston Purina Co., Eveready Battery Co. 3/	Marietta, OH				X	Do.

1/ FeMn, ferromanganese; SiMn, silicomanganese; Mn, manganese metal; MnO_2, synthetic manganese dioxide.

2/ Name changed to Erachem Comilog Inc. as of January 1, 2001.

3/ Spun off into Energizer Holdings, Inc., as of April 1, 2000.

TABLE 4
U.S. CONSUMPTION, BY END USE, AND INDUSTRY STOCKS OF MANGANESE FERROALLOYS AND METAL IN 200(

(Metric tons, gross weight)

End use	Ferromanganese			Silico-manganese	Manganese metal
	High carbon	Medium and low carbon	Total		
Steel:					
Carbon	125,000	101,000	225,000	74,600	1,340
High-strength, low-alloy	22,700	4,120	26,800	4,930	(2/)
Stainless and heat-resisting	13,700	(2/)	13,700	6,350	1,530
Full alloy	15,500	6,610	22,100	19,600	(2/)
Unspecified 3/	299	332	631	275	195
Total	177,000	112,000	289,000	106,000	3,060
Cast irons	8,660	503	9,160	1,340	5
Superalloys	W	W	W	--	W
Alloys (excluding alloy steels and superalloys)	1,570	629	2,200	(4/)	18,300 5/
Miscellaneous and unspecified	--	W	W	(4/)	W
Total consumption	187,000	113,000	300,000	107,000 6/	21,400
Total manganese content 7/	146,000	90,200	236,000	70,700	21,400
Stocks, December 31, consumers and producers	11,300	20,200	31,500	10,700	4,750

W Withheld to avoid disclosing company proprietary data; included with "Alloys (excluding alloy steels and superalloys)." -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Withheld to avoid disclosing company proprietary data; included with "Steel: Unspecified."
3/ Includes electrical and tool steel, and items indicated by (2/).
4/ Withheld to avoid disclosing company proprietary data.
5/ Approximately 85% of this combined total was for consumption in aluminum alloys.
6/ Internal evaluation indicates that silicomanganese consumption is considerably understated.
7/ Estimated based on typical percent manganese content.

TABLE 5
U.S. EXPORTS OF MANGANESE ORE, FERROALLOYS, AND METAL, BY COUNTRY 1/

Country	1999		2000	
	Gross weight (metric tons)	F.a.s. value (thousands)	Gross weight (metric tons)	F.a.s. value (thousands)
Ore and concentrates with 20% or more manganese:				
Canada	1,250	$332	4,160	$1,020
Germany	--	--	589	278
Italy	--	--	350	172
Norway	--	--	333	136

e/ Estimated. r/ Revised. XX Not applicable.
1/ World totals and estimated data are rounded to no more than three significant digits; may not add to totals shown.
2/ Table includes data available through July 26, 2001. Data pertain to concentrates or comparable shipping product, except that in a few instances the best data available appear to be for crude ore, possibly after some upgrading.
3/ In addition to the countries listed, Burkina Faso, Cuba, Panama, and Sudan may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels.
4/ May be average content of each year's production rather than for content of typical products.
5/ Metallurgical ore.
6/ Reported figure.
7/ Production of beneficiated ore as reported in Sumário Mineral (Brasilia).
8/ Includes manganiferous ore.
9/ Calculated metal content includes allowance for assumed moisture content.
10/ Sales.
11/ Much of India's production grades below 35% Mn; content averaged 38.3% Mn for fiscal years 1998-99 through 1999-2000.
12/ Mostly oxide nodules; may include smaller quantities of direct-shipping carbonate and oxide ores for metallurgical and battery operations.
13/ Category represents the combined totals of Bosnia and Herzegovina, Bulgaria, Burma, Chile, Colombia, Egypt, Georgia, Greece, Hungary, Indonesia, Iran, Italy (from wastes), Japan (low-grade ore), Malaysia, Morocco, Namibia, Romania, Russia (crude ore), Thailand, and Turkey.

e/ Estimated. r/ Revised. -- Zero.

1/ Table includes data available through July 25, 2001.

2/ World totals and estimated data are rounded to no more than three significant digits; may not add to totals shown.

3/ In addition to the countries listed, Iran is believed to have produced ferromanganese and silicomanganese, but production figures are not reported; general information is inadequate for the formulation of reliable estimates of output levels. Production of manganese ferroalloys, ferrosilicon, and silicon metal began in 1996 for Saudi Arabia, but data for actual production were not available. Data for U.S. production of manganese ferroalloys are not included to avoid disclosing company proprietary data.

4/ Ferromanganese includes, if any, silicomanganese.

5/ Silicomanganese includes, if any, silicospiegeleisen.

6/ Salable products from Autlán.

7/ Reported figure.

8/ Russia is believed to have produced some silicomanganese during 1996-99, but data for actual production were not available.

MERCURY

By Robert G. Reese, Jr.

Domestic survey data and tables were prepared by Adam A. Wario, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

As has been the case for more than a decade, recycled mercury-containing devices accounted for essentially all domestic mercury production in 2000. No domestic mine produced mercury as its primary product. Several companies were engaged in mercury refining, the three largest being in the Eastern and Central United States. Chlorine-caustic soda production was again the largest end use for mercury.

Legislation and Government Programs

The U.S. Geological Survey (USGS) in 2000 was directly involved in a broad range of national and international studies related to mercury and its distribution and mobility in the environment. Activities included data collection, long-term assessments, ecosystem analysis, predictive modeling, and process research on the occurrence, distribution, recycling, and fate of mercury. Much of this work was conducted in partnership with other Federal and State agencies.

During 2000, the USGS published a map showing the distribution of mercury in the Warrior coalfield in Alabama (Goldhaber and others, 2000). Using data from over 900 chemical analyses contained in the USGS National Coal Resources Data System, the authors found that the Warrior coal field contained higher levels of mercury and a suite of other trace elements when compared with the average for all U.S. coal. The map used three-dimensional plots of Warrior coalbeds to show mercury abundance and concentration.

On November 2, the U.S. Environmental Protection Agency (EPA) announced a ban on discharges of various bio-accumulative chemicals, including mercury, in the Great Lakes Basin. Under the ban, the discharges into mixing zones would be phased out over a 10-year period, while new discharges were banned immediately. Mixing zones are areas where toxic chemical discharges are permitted to mix with receiving waters and be diluted. EPA also announced plans to develop regulations covering discharges of bioaccumulative chemicals, including mercury, through mixing zones in 2001 (U.S. Environmental Protection Agency, 2000a).

On December 14, EPA announced plans to begin regulating mercury emissions from coal-fired powerplants. The Agency plans to announce proposed regulations during 2003 and to issue final regulations in 2004 (U.S. Environmental Protection Agency, 2000b).

Production

Since 1990, no domestic mine has produced mercury as its primary product. Owing in part to regulations controlling mercury discharges to the environment, however, some domestic mines and plants recovered small amounts of mercury. These mines and plants were located in areas that historically produced large amounts of mercury, such as California, Nevada, and Utah.

Nearly all the mercury produced in the United States was derived from secondary sources, including spent batteries, mercury vapor and fluorescent lamps, switches, dental amalgams, measuring devices, control instruments, and laboratory and electrolytic refining wastes. The secondary processors typically use high-temperature retorting to recover mercury from compounds and distillation to purify the contaminated liquid mercury metal. Among the largest producers of refined mercury from scrap material were the following companies: Bethlehem Apparatus Co. Inc., Hellertown, PA; D.F. Goldsmith Chemical and Metal Corp., Evanston, IL; and Mercury Waste Solutions, Inc., Minneapolis, MN.

Consumption

The USGS estimated that the electrolytic production of chlorine and caustic soda and electrical applications were the largest uses for mercury in the United States, accounting for approximately 50% and 25% of domestic consumption, respectively. Only in dental applications, where it is the most

Mercury in the 20th Century

In 1901, the United States, with an output of more than 1,000 metric tons, was the world's largest mercury producer. Mercury imports were insignificant, and with shipments of nearly 390 tons, the United States was a net mercury exporter. Among the largest uses for mercury during the first half of the century were the production of explosives, pharmaceuticals, various fungicides and bactericides, dental amalgams, batteries, switches, and measuring and control instruments such as barometers. For much of the century, the United States remained among the largest mercury-producing countries. Because of mercury's toxic nature, however, various rules and regulations were enacted, especially in the 1970s, to eliminate or curtail human exposure to mercury.

By the end of the century, there were no longer any producing mercury mines in the United States, and domestic production was limited to the metal recovered from scrap materials. In 2000, the United States was a net mercury exporter, with most of the material shipped to India and the Netherlands. It is estimated that the largest domestic use for mercury is in the production of chlorine and caustic soda.

Digitized by Google

cost-effective and longest lasting dental cavity-filler, has the quantity of mercury consumed remained steady.

World Review

During the past 10 years, annual world mercury production has averaged about 2,500 t, nearly all of which was produced at mines where mercury is the primary product. Most countries do not report their mercury production, and world production values have a high degree of uncertainty. In 2000, about 10 countries produced mercury, with Kyrgyzstan and Spain the dominant producing nations. In some countries, a few base-metal operations recover small quantities of mercury to meet environmental standards and avoid environmental releases of the metal.

In June, a contract transporter for the Yanacocha gold mine in Peru spilled about 151 kilograms of mercury near the town of Choropampa. Minera Yanacocha S.R.L. undertook a comprehensive health and environmental remediation program, agreed to provide a number of public works for nearby communities, and paid a fine of approximately $500,000 as compensation for the spill (Newmont Mining Corp., 2001, p. 24).

Outlook

Ever stricter environmental regulations and the development of new technology are expected to be the primary factors affecting mercury supply and demand in the near future. Environmental standards and technological advances likely will work in tandem to reduce the demand for mercury in commercial products. Even as the per-unit mercury product content declines, regulations on the disposal of mercury will prompt more recycling of mercury-bearing material to recover the contained mercury. Consequently, secondary mercury is expected to remain the principal component of domestic supply. Other potential sources of domestic supply could include mercury in the National Defense Stockpile and the mercury recovered from the dismantling of mercury cells in some chloralkali operations.

MICA

By James B. Hedrick

Domestic survey data and tables were prepared by Raymond I. Eldridge III, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

The mica group currently represents 37 phyllosilicate minerals that have a layered or platy texture (Rieder and others, 1998). (Phyllo is derived from the Greek word *phyllon*, meaning leaf.) The commercially important micas are muscovite and phlogopite.

The value of mica is in its unique physical properties. The crystalline structure of mica forms layers that can be split or delaminated into thin sheets. These sheets are flexible, elastic, platy, transparent to opaque, resilient, reflective, refractive, dielectric, chemically inert, insulating, lightweight, and hydrophilic. Mica also is stable when exposed to electricity, light, moisture, and extreme temperatures. Based on its greater abundance and superior electrical properties, muscovite is the principal mica used by industry. Phlogopite remains stable at higher temperatures and is used in applications where a combination of high-heat stability and electrical properties is required. Muscovite and phlogopite are used in sheet and ground forms.

In 2000, about 101,000 metric tons (t) of scrap and flake mica was produced in the United States, 6% more than that of 1999 (tables 1, 3). Ground mica sales were 112,000 t, a slight increase in tonnage of 1% compared with 1999, and were valued at $37.5 million. Essentially all sheet mica used in the United States was imported, and India was the major supplier. Consumption of muscovite block mica decreased to 5.9 t valued at $132,000. Consumption of mica splittings decreased to 583 t in 2000 from 786 t in 1999. Worked and unworked sheet mica exports decreased to 1,280 t in 2000 from 1,290 t in 1999, and the value decreased by 7% to $17.4 million. U.S. imports of worked and unworked sheet mica increased to 5,710 t in 2000 from 4,550 t in 1999, and the value decreased by 2% to $14.1 million.

Legislation and Government Programs

The National Defense Authorization Act for Fiscal Year 2000 (Public Law 106-65), which was enacted on October 5, 1999, did not change the previous authorization for the disposal of stocks of mica in excess of the National Defense Stockpile (NDS) goals. Stocks of mica classified as excess to goal at the end of fiscal year 1999 (September 30, 1999) were all subject to either no disposal limits or were below the disposal limits previously specified. Excess NDS mica stocks were 283,322 kilograms (kg) (624,619 pounds) of muscovite block (stained and better), 702 kg (1,548 pounds) of muscovite film (1st and 2nd qualities), 5,232,975 kg (11,536,734 pounds) of muscovite splittings, 234,345 kg (516,643 pounds) of phlogopite splittings, and 53,498 kg (117,942 pounds) of phlogopite block. The law authorized the transfer of no more than $150 million from the NDS Transaction Fund to the operation and maintenance accounts (no more than $50 million each) of the Army, Navy, and Air Force (section 304). The law also obligated no more than $78.7 million of the NDS Transaction Fund for the operation of the NDS program, including disposal of hazardous materials that are environmentally sensitive.

The Floyd D. Spence National Defense Authorization Act for

Mica in the 20th Century

In 1900, mica production was at an all-time high owing to increased use of small-sized mica, which was previously considered a waste product. Much of this small-sized material was recovered from scrap heaps at existing mine sites to complement the shop scrap used to meet the flourishing demand from the electric industry. At the turn of the 20th century, sheet mica was used primarily in stove windows, chimneys and lampshades on open-flame gas and oil lights, and furnace peephole covers. Most of these uses of large-sized mica sheet were in decline with the advent of the domestic electric industry. The demand for small-sized material for use as insulators in electric motors, coil insulators in magnetos in early gasoline engines, insulators in spark plugs, and in nonelectric phonographs, which had a stylus set in a mica diaphragm, was increasing. Other sheet mica uses were as windows in horse-drawn buggies and in boiler gauges. Wet-ground mica was used in turn-of-the-century wallpaper, and coarsely ground material was used as an artificial snow during the winter holidays. The primary use of dry-ground mica was in the rolled roofing and asphalt industry where it was used to prevent sticking. Dry-ground mica was also used as an additive in axle grease and special lubricants and in quack medicines and elixirs. In the early days of electric power generation, sheet mica was the only material available with electrical and mechanical properties suitable to operate at the temperatures necessary for the efficient functioning of the electrical equipment. In 1900, U.S. production of sheet mica was 207 metric tons valued at $92,758.

In 2000, U.S. production of sheet mica was negligible. Imports of sheet mica were 5,710 tons valued at $14.1 million. Sheet mica was used primarily in electric motors, with lesser amounts used as spacers and washers in electronics and as insulation in toasters, electric hair dryers, and hair curling irons. Sheet mica was also used in stove windows, lamp shades, and in turn-of-the-century reproduction wallpaper. Ground mica production in 2000 was 112,000 tons valued at $37.5 million. Major uses of dry-ground mica were in house paints and in joint compound for drywall. Wet-ground mica was used in pearlescent paints for automobile coatings, to add sparkle and shimmer in cosmetics, in plastic reinforcement fillers, in nylon and polyester resins, and in polypropylene composites.

Digitized by Google

Fiscal Year 2001 (Public Law 106-398), which was enacted on October 30, 2000, continued the funding of $150 million ($50 million each) of the operation and maintenance accounts of the Army, Navy, and Air Force by the NDS Transaction Fund. The law obligated no more than $71 million of the NDS Transaction Fund for the operation of the NDS program, including disposal of hazardous materials that are environmentally sensitive, a decrease of $7.7 million from that of 1999. The revised Annual Material Plan for fiscal year 2000 authorized the disposal of 1,025,119 kg (2,260,000 pounds) of mica (all types) from the NDS classified as excess to goal. Stocks of mica classified as excess to goal at the end of fiscal year 2000 (September 30, 2000) were all subject to either no disposal limits or were below the disposal limits previously specified. Excess NDS mica stocks were 51,836 kg (114,279 pounds) of muscovite block (stained and better), 674 kg (1,485 pounds) of muscovite film (1st and 2nd qualities), 4,168,229 kg (9,189,371 pounds) of muscovite splittings, 232,554 kg (512,693 pounds) of phlogopite splittings, and 15,902 kg (35,058 pounds) of phlogopite block (table 2).

Production

Domestic mine production data for mica are developed by the U.S. Geological Survey from four separate voluntary surveys. Of the 14 operations to which the "Crude Scrap and Flake Mica" production form (including sericite production) was sent, 9 operations responded. Of the 16 operations to which the "Ground Mica" form was sent, 6 operations responded and 1 had not started grinding (excludes low-grade ground sericite production). Of the five surveyed operations to which the "Mica Block and Film" consumption form was sent, four operations responded. Of the nine surveyed operations to which the "Mica Splittings" consumption form was sent, seven operations responded. Consumption for the nonrespondents was estimated by using prior-year production data. Individual company production and consumption data are withheld to avoid disclosing company proprietary data.

AZCO Mining Inc. reported that it had completed a production run at the end of 1999 at its mica mine at Black Canyon, AZ. The mine produced an initial run of 7,000 t of high-grade green-colored muscovite. The stockpile of ore from the Black Canyon Mica Mine was expected to be sufficient to supply AZCO's Glendale processing plant at Glendale, AZ, with feed for a full year. The mine, which is on Federal land, was expected to produce muscovite from a swarm of pegmatite dikes that occur over a distance of 1,524 meters (m) with widths varying from 3 to 18 m (AZCO Mining Inc., 2000b).

AZCO Mining Inc. announced that its subsidiary, Azco Mica Inc. of Glendale, AZ, began production of a wet-ground cosmetic grade mica. The mica is a pearl-white muscovite mica with high luster and translucence that is available in two particle ranges, 1 to 50 microns and 5 to 70 microns. The company also has the capability to produce high aspect ratio mica that is used in plastics and pearlescent paints (AZCO Mining Inc, 2000a).

Zemex Industrial Minerals Inc. (ZIM), a subsidiary of Zemex Corp., announced that its phlogopite operations in Canada had a very strong year. This fact, however, was offset by the fact that ZIM had to put its Spruce Pine, NC, mica operation, which it purchased from Aspect Minerals, Inc. in 1998, on a care and maintenance basis because of decreased availability of byproduct feed material. Feed for the plant had relied more heavily on mined byproduct; however, inconsistencies in the grade and quality of the ores in conjunction with increased processing costs resulted in the decision to idle the facility (Zemex Corp., 2001).

Oglebay Norton Specialty Minerals, Inc. (ONSM), a subsidiary of Oglebay Norton Co., produced dry- and wet-ground mica from its mining and processing operations near Kings Mountain, NC, and Velarde, NM. ONSM, which acquired Franklin Industries' mica business in 1999, increased its earnings because demand was strong for mica products in 2000 (Oglebay Norton Co., 2001).

Scrap and Flake Mica.—In 2000, 8 domestic companies with 11 mines in 6 States produced scrap and flake mica (excluding low-grade sericite). The United States was one of the world's primary producers with 101,000 t (tables 1, 3). North Carolina remained the major producing State, with 46% of domestic production, and the remainder was produced in Georgia, New Mexico, South Carolina, South Dakota, and Virginia. Mica was recovered from mica schist, high-quality sericite schist, weathered pegmatites, a gemstone pegmatite, and as a coproduct of feldspar and kaolin.

The scrap and flake mica producers, in alphabetical order, were AZCO Mining Inc., Black Canyon, AZ (contract basis); Engelhard Corp., Hartwell, GA; The Feldspar Corp., a Zemex Industrial Minerals company, (2 mines) Spruce Pine, NC; K-T Feldspar Corp., Spruce Pine, NC; Oglebay Norton Specialty Minerals, Inc., Kings Mountain, NC, and Velarde, NM; The Mineral Mining Co. Inc., Kershaw, SC; Pacer Corp., Custer, SD; Tinton Enterprises, Spearfish, SD; Unimin Corp., Spruce Pine, NC; and Zemex Mica Corp., a Zemex Industrial Minerals company, Micaville, NC.

Ground Mica.—In 2000, 11 companies operated 16 grinding plants in 6 States; 11 plants produced dry-ground mica, and 5, wet-ground mica. The four largest ground mica companies, including one company with four plants, accounted for 64% of the total of 112,000 t (table 4).

Dry-ground mica producers, in alphabetical order, were Asheville Mica Co., Asheville, NC; Georgia Industrial Minerals, Inc., Deep Step, GA; AZCO Mining Inc., Glendale, AZ; The Mineral Mining Co. Inc., Kershaw, SC; Oglebay Norton Specialty Minerals Inc. (2 plants), Kings Mountain, NC, and Velarde, NM; Pacer Corp., Custer, SD; Piedmont Minerals Corp., Hillsborough, NC; USG Corp., Spruce Pine, NC; and Zemex Mica Corp., a Zemex Industrial Minerals company, Spruce Pine, NC.

Wet-ground mica producers, in alphabetical order, were AZCO Mining Inc., Glendale, AZ; Engelhard Corp., Hartwell, GA; Oglebay Norton Specialty Minerals Inc., Kings Mountain, NC; and Zemex Mica Corp., a Zemex Industrial Minerals company, Bakersville, NC.

Sheet Mica.—Small quantities of muscovite sheet and scrap mica were produced as a byproduct by Morefield Gem Mine, Inc., in Amelia Co., VA. The pegmatite was mined primarily for gemstones and mineral samples using underground methods. The mine also produced biotite and zinnwaldite mica.

Consumption

Statistics on domestic mica consumption are developed by surveying various processors and manufacturers, evaluating import-export data, and analyzing Government stockpile shipments.

Digitized by Google

Sheet Mica.—Sheet mica is used principally in the electronic and electrical industries. Its usefulness in these applications is derived from its unique electrical and thermal insulating properties and its mechanical properties, which allow it to be cut, punched, stamped, and machined to close tolerances.

The largest use of block mica is as an electrical insulator in electronic equipment. High-quality block mica is processed to line the gauge glasses of high-pressure steam boilers because of its transparency, flexibility, and resistance to heat and chemical attack. Other uses include diaphragms for oxygen-breathing equipment, marker dials for navigation compasses, optical filters, retardation plates in helium-neon lasers, pyrometers, thermal regulators, and stove and kerosene heater windows. Specialized applications for sheet mica are found in aerospace components in ground- and air-launched missile systems, optical instrumentation, laser devices, medical electronics for radiation treatment, and radar systems.

Only high-quality muscovite film mica is used as a dielectric in capacitors. The highest quality film is used to manufacture capacitors for calibration standards. The next grade down is used in transmitting capacitors. Receiving capacitors use a slightly lower grade of high-quality muscovite.

In 2000, consumption of muscovite block (ruby and nonruby) totaled 5,940 kg, a 10% decrease compared with that of 1999 (table 5). Stained and lower than stained quality remained in greatest demand, accounting for 96.1% of ruby mica block. Consumption of nonruby mica block was split—88% for stained quality and 12% for good quality. The use of block mica was lower as demand in electronic and nonelectronic applications decreased.

In 2000, five companies continued to consume muscovite block and film in five plants in four States—two in North Carolina and one each in New Jersey, Ohio, and Virginia. In 2000, mica splittings represented the largest part of the sheet mica industry in the United States. Consumption of muscovite and phlogopite splittings decreased by 26% to 583 t (table 6). Muscovite splittings from India accounted for essentially all of the domestic consumption. The remainder of consumption was primarily phlogopite splittings imported from Madagascar. Muscovite and phlogopite splittings were fabricated into various built-up mica products by nine companies operating nine plants in seven States.

Built-Up Mica.—Produced by mechanical or hand setting of overlapping splittings and alternate layers of binders and splittings, built-up mica is primarily used as an electrical insulation material. Major products are bonding materials, flexible plate, heater plate, mica paper, molding plate, segment plate, and tape (table 7).

Segment plate acts as insulation between the copper commutator segments of direct-current universal motors and generators. Phlogopite built-up mica is preferred because it will wear at the same rate as the copper segments. Although muscovite has a greater resistance to wear, it causes uneven ridges that may interfere with the operation of a motor or generator. Consumption of segment plate was 10 t in 2000 (table 7).

Molding plate is sheet from which v-rings are cut and stamped for use in insulating the copper segments from the steel shaft ends at the end of a commutator. Molding plate is also fabricated into tubes and rings for insulation in transformers, armatures, and motor starters. Consumption of molding plate increased by 11% to 194 t in 2000 from 175 t in 1999 (table 7).

Flexible plate (cold) is used in electric motor and generator armatures, field coil insulation, and magnet and commutator core insulation. Mica consumption in flexible plate decreased to 61 t in 2000 from 125 t in 1999 (table 7).

Heater plate is used where high-temperature insulation is required. Consumption of mica in heater plate increased by 1% in 2000 compared with that of 1999.

Some types of built-up mica have the bonded splittings reinforced with cloth, glass, linen, muslin, plastic, silk, or special paper. These products are very flexible and are produced in wide, continuous sheets that are either shipped rolled or cut into ribbons, tapes, or trimmed to specified dimensions. Built-up mica products are also corrugated or reinforced by multiple layering.

The total amount of built-up mica that was consumed or shipped was 358 t, a decrease of 32.7% compared with that of 1999 (table 7). In 2000, molding plate and flexible plate (cold) were the major end products and accounted for 54% and 17% of the total, respectively.

Mica Paper (Reconstituted Mica).—Primary uses for mica paper are the same as those for built-up mica. Three companies consumed scrap mica to produce mica paper. The principal source of the scrap was India. In 1999, manufacturing companies, in alphabetical order, were Corona Films Inc., West Townsend, MA; General Electric Co., Coshocton, OH; and U.S. Samica Corp., Rutland, VT.

Ground Mica.—The largest domestic use of dry-ground mica was in joint compound for filling and finishing seams and blemishes in gypsum wallboard (drywall) (table 4). The mica acts as a filler and extender, provides a smooth consistency, improves the workability of the compound, and provides resistance to cracking. In 2000, joint compound accounted for 44% of dry-ground mica consumption.

In the paint industry, ground mica is used as a pigment extender that also facilitates suspension, reduces chalking, prevents shrinking and shearing of the paint film, increases resistance of the paint film to water penetration and weathering, and brightens the tone of colored pigments. Mica also promotes paint adhesion in aqueous and oleoresinous formulations. Consumption of dry-ground mica in paint, its second largest use, accounted for 30% of the 2000 total.

Ground mica is used in the well-drilling industry as an additive to drilling muds. The coarsely ground mica flakes help prevent the loss of circulation by sealing porous sections of the drill hole.

The rubber industry uses ground mica as an inert filler and a mold release compound in the manufacture of molded rubber products, such as tires and roofing. The platy texture acts as an antiblocking, antisticking agent. Rubber mold lubricant accounted for 4.8% of dry-ground mica use in 2000.

The plastics industry uses dry-ground mica as an extender and filler, especially in parts for automobiles for lightweight insulation to suppress sound and vibration. Mica is used in plastic automobile fascia and fenders as a reinforcing material, providing improved mechanical properties, increased strength, stiffness, and dimensional stability. Mica-reinforced plastics also have high-heat dimensional stability, reduced warpage, and the best surface properties of any filled plastic composite. In 2000, consumption of dry-ground mica in plastic applications accounted for 4.4% of the market, higher than the 2.9% consumed in 1999 (table 4).

Dry-ground mica is used in the production of rolled roofing

Digitized by Google

and asphalt shingles where it serves as a surface coating to prevent sticking of adjacent surfaces. The coating is not absorbed by freshly manufactured roofing because mica's platy structure is unaffected by the acid in asphalt or by weathering conditions. As a rubber additive, mica reduces gas permeation and improves resiliency.

Mica is also used in decorative coatings on wallpaper, concrete, stucco, and tile surfaces. It is also used as an ingredient in some special greases, as a flux coating on welding rods, and in foundry applications as coatings for core and mold release compounds, mold washes, and facing agents.

Wet-ground mica, which retains the brilliancy of its cleavage faces, was used primarily in pearlescent paints by the automotive industry. Its reflective and refractive properties were also used in cosmetics where it was used as an ingredient in eye shadow, body and hair glitter, face makeup, and fingernail polish.

Stocks

Government stocks of mica in the NDS comprised stockpile-grade muscovite block, stained and better; muscovite film, 1st and 2nd qualities muscovite splittings; phlogopite block; and phlogopite splittings. NDS stocks of muscovite block, muscovite film, and muscovite and phlogopite splittings were available for sale from the Defense National Stockpile Center, Fort Belvoir, VA. Yearend 2000 stocks of various types of mica in the NDS are listed in table 2.

Reported yearend industry stocks of muscovite mica block (ruby and nonruby) decreased to 17.8 t in 2000 from 19.3 t in 1999. Industry stocks of muscovite and phlogopite mica splittings decreased to 404 t at yearend 2000 from 411 t at yearend 1999 (table 6).

Prices

Sheet mica prices vary with grade and can range from less than $1 per kilogram for low-quality mica to more than $2,000 per kilogram for the highest quality. The average values of muscovite sheet mica consumed in the United States in 2000 compared with the previous year were as follows: block (ruby and nonruby) increased to $22 per kilogram from $21 per kilogram in 1999, and muscovite splittings increased to $1.60 per kilogram from $1.51 per kilogram in 1999.

The average value of phlogopite block increased to $14.95 per kilogram in 2000 from $12.82 per kilogram in 1999. The average value of phlogopite splittings increased to $4.89 per kilogram in 2000 from $4.69 per kilogram in 1999.

In 2000, the average U.S. value of crude flake mica, including high-quality sericite, increased to $136 per ton (table 1). The average value for North Carolina flake mica decreased to $98 per ton in 2000. The value of dry-ground mica decreased 12% to average $169 per ton, and wet-ground mica also decreased 12% to average $751 per ton (table 1).

Foreign Trade

Demand for mica increased in U.S. and foreign markets in 2000. Foreign trade decreased, with the value of U.S. exports of mica decreasing by 9% to $22.4 million as the quantity decreased by 8% to 11,500 t. Imports of mica, however, increased by 12% to 34,000 t with the value of U.S. imports of mica increasing by 5% to $28.1 million (table 13).

Domestic ground mica exports increased to 8,880 t, up 1,560 t from that of 1999 (table 8). Exports of crude and rifted mica decreased to 651 t, primarily the result of decreased sheet mica sales from the NDS. Exports of worked mica sheet in 2000 increased by 27% to 1,070 t (table 9). The value of U.S. exports of worked mica sheet increased to $17.1 million, 2.8% higher than that of 1999.

India continued to supply the United States with essentially all of its supply of sheet and paper-quality scrap mica. Imports for consumption of unworked split block, film, splittings, and mica sheet catagorized as "Other," were about 9,784 t, 37% higher than that of 1999 (table 10).

About 22,100 t of ground mica were imported in 2000, mostly from Canada (table 11). Worked mica imports were 1,310 t, 27% lower than those of 1999 (table 12).

Outlook

The outlook for ground mica is for production growth of 1% to 3% per year. The major markets for ground mica—joint compounds and paints—are mature and relatively stable, and growth is tied to new housing starts and interest rates. To a lesser extent, widespread natural disasters also affect the market, creating immediate demand for residential building materials. Demand is also responsive to automobile production because interior and exterior parts typically contain dry-ground mica, and exterior surfaces are painted with wet-ground pearlescent pigments and mica-containing coatings.

In 2001 and 2002, domestic demand for crude and ground mica is expected to increase slightly. Demand for wet-ground mica is expected to improve significantly, at up to twice the rate of dry-ground mica, in the short term to meet increasing demand for plastic reinforcement fillers, nylon and polyester resins, polypropylene composites, pearlescent paints, and cosmetics. Markets for dry-ground mica are forecast to grow by as much as 3% per year through the year 2005, unless interest rates and prices rise sufficiently to slow demand for new housing and automobiles. Wet-ground mica is expected to show moderate growth in the long term as demand from the cyclical automotive industry, which uses increasing amounts of pearlescent paint and engineered mica-bearing plastics, increases.

Demand for block mica is expected to grow slowly over the next several years as demand increases in a few specialty markets. A shortage of high-quality block mica is expected to continue because of the generally low percentage of high-quality mica in currently (2000) mined deposits (pegmatites).

Consumption of mica splittings, the principal type of sheet mica consumed in the United States, decreased sharply throughout the 1960s and 1970s and leveled off in the 1980s and 1990s in the range of 700 to 1,000 t per year (t/yr). With no new uses and many substitute materials, no substantial growth is expected. Consumption of mica splittings is expected to remain in the range of 500 to 900 t/yr.

MOLYBDENUM

By John W. Blossom

Domestic survey data and tables were prepared by Barbara J. McNair, statistical assistant and the world production table was prepared by Linder Roberts, international data coordinator.

Molybdenum is a refractory metallic element used principally as an alloying agent in steel, cast iron, and superalloys to enhance hardenability, strength, toughness, and wear and corrosion resistance. To achieve desired metallurgical properties, molybdenum, primarily in the form of molybdic oxide or ferromolybdenum, is frequently used in combination with or added to chromium, columbium, manganese, nickel, tungsten, or other alloy metals. The versatility of molybdenum in enhancing a variety of alloy properties has ensured it a significant role in contemporary industrial technology, which increasingly requires materials that are serviceable under high stress, expanded temperature ranges, and highly corrosive environments. Moreover, molybdenum finds significant usage as a refractory metal in numerous chemical applications, including catalysts, lubricants, and pigments. The variety of uses for molybdenum materials, few of which afford acceptable substitution, has resulted in demand that is expected to grow at a greater rate than that of most other alloying metals.

Distribution of molybdenum reserves and productive capacity was concentrated in a few countries of the world. World mine output was estimated to be 129,000 metric tons (t) (molybdenum contained in concentrate), of which, in descending order of production, the United States, Chile, China, Peru, Mexico, and Canada provided 92%. These countries also possessed about 90% of the estimated 12 million metric tons of molybdenum in the world reserve base. [All units are metric tons of contained molybdenum unless otherwise noted.]

Production

Domestic production data for molybdenum were derived by the U.S. Geological Survey by means of three separate voluntary surveys. These surveys are Molybdenum Ore and Concentrate (annual), Molybdenum Concentrate (monthly), and Molybdenum Products and Molybdenum Concentrates (monthly). Surveys are sent to all operations that produce molybdenum ore and products. All eight operations to which surveys were sent responded, representing 100% of the U.S. production shown in table 1.

In 2000, U.S. mine production of molybdenum concentrate was 41,100 t, a decrease from 42,400 t in 1999. World mine production of molybdenum concentrate increased to 129,000 t in 2000 from 128,000 t in 1999. U.S. share of world production was 31% in 2000, 33% in 1999. Net production of molybdenum products increased by 500 t in 2000. (See tables 1, 2, 7-8.)

Thompson Creek Mining Company announced in January 2001, that it would curtail operations at the Thompson Creek mine near Challis, ID (Thompson Creek Mining Company, 2001). This reduction in mining activity was necessitated by near-record-low prices in the molybdenum industry, reduction in demand due to a slowing U.S. economy, and the continuing export by China of increasing quantities of molybdenum products into the world market, according to Thompson Creek Mining.

The mine planned to produce 2.7 million kilograms in 2001, which was about one-half of its production rate in 2000 and less than one-third of its capacity. Thompson Creek said it would continue to supply long-term customers and will emphasize sales of value-added products.

The new mine plan reportedly was to entail the elimination of 65 jobs out of a work force of 125. Severed employees were to continue to receive salary and benefits through March 17, 2001. Thompson Creek Mining Company is a subsidiary of Thompson Creek Metals Co. The company also operates the Endako molybdenum mine in Canada as well as the Langeloth metallurgical processing facility in Pennsylvania.

Molybdenum in the 20th Century

At the beginning of the 20th century, there was little demand for molybdenum minerals, except for limited use in the manufacture of chemical reagents. One pound of contained metallic molybdenum in molybdenite ore was worth about $0.10. Most bonanza ores were exhausted by 1900, and molybdenum mining's future rested squarely on its ability to mass mine large deposits of low-grade ores and to concentrate them economically. Flotation separation technology enabled this to be done. Average annual U.S. molybdenum production during the first decade of the century was about 40 metric tons per year; however, production was reported only for 1901-1903.

By 1910, the price of molybdenum was nudging $2.20 per kilogram, as the molybdenum market was slowly coming to life. As World War I raged in Europe in 1914, German, British, French, and Russian armament manufacturers competed to buy all available molybdenum from the only European source, Kven Mine and mill at Knaben, Norway. U.S. production and price of molybdenum peaked at 391 tons in 1918 with the end of World War I. New uses in the steel and chemical industry grew with expanding population. The U.S. production of molybdenum reached a peak of 68,400 tons in 1980. The lowest U.S. production since 1980 was 15,200 tons in 1993. At the end of the 20th century, U.S. production was trending downward. Molybdenum was being used in many more applications, such as stainless steel, catalysts and lubricants, with reported consumption exceeding 20,000 tons per year in the last decade of the century.

Consumption

In 2000, consumption of molybdenum concentrate was 33,800 t, a decreased 700 t compared with that of 1999. Domestic mine production of molybdenum concentrate was roasted, exported for conversion, or purified to lubrication-grade molybdenum disulfide. Technical-grade molybdic oxide consumption decreased by about 3% in 2000 compared with that of 1999. Oxide was the chief form of molybdenum used by industry, particularly in stainless and alloy steel, cast iron, and superalloys. However, ferromolybdenum comprised 67% of the molybdenum-bearing forms used to make steel, a 1% decrease from that of 1999. Some of the oxide was, however, converted to other molybdenum products, such as ferromolybdenum, high-purity oxide, ammonium and sodium molybdate, and metal powder. (See tables 1, 3.)

Stocks

In 2000, producer plus consumer industry stocks were 11,400 t, a decrease of 600 t compared with those of 1999. Inventories of molybdenum in concentrate at mine and plant decreased by about 550 t. Producer stocks of molybdenum in products, such as oxide, ferromolybdenum, molybdate, metal powders, and other types, increased by about 20 t. Consumer stocks of molybdenum contained in various materials decreased by 40 t compared with those of 1999. Stocks of 11,400 t represented about a 35-week supply. Supply is calculated as reported stocks (table 1) divided by annual consumption (table 3).

Prices

Prices are from Platt's Metals Week (2000) and are in U.S. dollars per kilogram of contained molybdenum. At the beginning of 2000, the prices were molybdenum molybdic oxide (MoX), $5.534 and ferromolybdenum (FeMo), $7.716. At the beginning of the second quarter, the prices were MoX, $5.567 and FeMo, $7.606. At the start of the third quarter, the prices were MoX, $6.228 and FeMo, $7.937. At the start of the fourth quarter, the prices were MoX, $5.578 and FeMo, $7.606. At the end of the fourth quarter, the prices were MoX, $4.806 and FeMo, $6.779. The annual average prices were MoX, $5.638 and FeMo, $7.625.

Foreign Trade

Exports of molybdenum in concentrate and in molybdic oxide were about 15% lower than those of 1999; molybdenum concentrate exports were about 58% of domestic mine production. About 90% of reported exports of concentrates went to Belgium, Canada, Japan, the Netherlands, and the United Kingdom. In 2000, molybdenum exports collectively contained about 27,600 t of molybdenum and were valued at $159 million, a 15% decrease from $186 million in 1999.

The United States imported about 13,600 t of molybdenum contained in various materials, which was about 700 t more than those imported in 1999. Total value of all forms of molybdenum imported increased from $104 million in 1999 to $111 million in 2000. In terms of value, the major form imported was ferromolybdenum. Major import sources, in descending order of quantity imported, were United Kingdom, Chile, and China. (See tables 4, 5, 6.)

World Review

Capacity.—As of December 31, U.S. rated capacity for mines and mills was estimated to be 70,000 metric tons per year of contained metal. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate based on the physical equipment of the plant and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity included operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Reserves.—With a reserve base of molybdenum estimated to be 5.4 Mt, the United States had 45% of the world molybdenum reserve base. About 90% of U.S. reserves was in large porphyry or disseminated deposits mined or anticipated to be mined primarily for molybdenum; these deposits were in Alaska, Colorado, Idaho, Nevada, New Mexico, and Utah. Other molybdenum sources contribute insignificantly to U.S. reserves.

Most Canadian reserves of molybdenum are in British Columbia. Other Canadian reserves were associated with molybdenum and copper-molybdenum porphyry deposits in British Columbia and with minor sources in New Brunswick and Quebec.

Molybdenum reserves in Central America and South America were associated mainly with large copper porphyry deposits. Of several such deposits in Chile, the Chuquicamata and El Teniente deposits were among the world's largest and accounted for 85% of molybdenum reserves in Chile. Mexico and Peru had substantial reserves. La Caridad deposit in Mexico was a large producer. Numerous other copper porphyries that may contain recoverable quantities of molybdenum have been identified in Central America and South America. Many of these deposits were being actively explored and evaluated and could substantially add to reserves in the future.

Reserves of molybdenum in China and the Commonwealth of Independent States were estimated to be substantial, but definitive information about the current sources of supply or prospects for future development in these two areas was lacking.

Outlook

Because of abundant resources and adequate production capacity in China, Chile, the United States and other countries, the future requirement for molybdenum should be readily met by the world producers. The principal use for molybdenum will continue to be in chemicals/catalysts and as an additive in steel manufacturing in general, most importantly alloy and stainless steel. Strong growth in production of stainless steel and superalloys can be expected in the near term with generally healthy economic conditions over the next few years.

NICKEL

By Peter H. Kuck

Domestic survey data and tables were prepared by Barbara J. McNair, statistical assistant, and world production tables were prepared by Glenn J. Wallace, international data coordinator.

Producers continued to commission new mines and add capacity because of optimistic forecasts for long-term growth in demand for stainless steel and nickel-based batteries. More than 280,000 metric tons (t) of capacity (on a contained nickel basis) were scheduled to come on-stream between 2001 and 2007. In Western Australia, three new laterite mines were commissioned between 1998 and 2000, and at least three others were in various stages of development (Western Australian Department of Resources Development, 1999, p. 3-18; Griffiths, 2000). The three new laterite mines were refining the nickel on-site. However, two new sulfide mines in Western Australia were shipping concentrates or matte to Outokumpu Oyj's recently expanded smelting and refining complex in Finland. In addition to the expansion in Australia, new mining projects were at various stages of development in Brazil, Canada, Indonesia, New Caledonia, the Philippines, and Venezuela. Exports of primary nickel from Russia were up about 6% from 1999 levels. Russian exports exceeded demand inside the country by more than 9 to 1. Russian consumption of nickel has been severely depressed for the past 4 years largely because the former Soviet stainless steel industry has had problems shifting to a market-economy mode.

Stainless steel accounted for more than 60% of nickel consumption in the world. In the United States, however, this percentage was considerably lower and was closer to 40% because of the relatively large number of specialty metal industries in the country. Specialty uses included superalloys and other aerospace alloys, high-temperature nickel-chromium alloys, electrolytic plating, electroless plating, cupronickel alloys, and naval brasses.

Nickel in excess of 8% is needed to produce the austenitic structure in 300-series stainless steels. The nickel content of some austenitic grades can be as high as 22%. Duplex (ferritic-austenitic) steels generally contain only 2.5% to 5.0% nickel (Ni). Sometimes, smaller amounts of nickel (0.2% to 3.8%) are incorporated into low alloy steels to improve their resistance to atmospheric corrosion.

Legislation and Government Programs

Decontamination of Radioactive Nickel Metal.—For more than a decade, the U.S. Department of Energy (DOE) has been exploring ways of reusing nickel metal scrap contaminated with trace amounts of natural and manmade radioactive isotopes. DOE has some 6,000 t of volumetrically contaminated nickel stored at the East Tennessee Technology Park in Oak Ridge, TN. "Volumetrically contaminated" describes metal that has radioactive contamination dispersed throughout the mass of the

Nickel in the 20th Century

In 1900, refineries in New Jersey and New York recovered a total of 4 metric tons of nickel from byproduct matte produced at the Mine Lamotte lead smelter in Missouri. The bulk of U.S. nickel consumption, however, was met by cobalt-copper-nickel matte imported from Canada and processed into nickel oxide or metallic nickel at Bayonne and Camden, NJ. The nickel smelter at Sudbury, Ontario, shipped 23,287 tons of ore and matte, containing about 3,100 tons of nickel, to the United States in 1900. France and the German Empire were Canada's biggest competitors for nickel production between 1890 and 1905. Both European producers were heavily dependent on matte and ore from New Caledonia, where nickel laterite mining had begun in 1875. The most important use was the manufacture of nickel steel, a family of alloy steels containing 3% to 25% nickel. By 1900, nickel steel was being fabricated into armor plate, gun turrets, propeller shafts, crank shafts, and a variety of other parts for naval vessels. Shipbuilders also found that nickel-bronzes and nickel-brasses were relatively resistant to saltwater corrosion and made good vessel parts. Other important end uses were coins, cutlery, and plating. Most of the cutlery was being fabricated from German silver, a family of copper-zinc-nickel alloys.

Nickel had been a strategic and critical material in every major conflict fought by the United States since 1900, with the U.S. Government having to allocate or ration the metal in almost every instance. World War I caused world production of nickel steel to soar. The development of stainless steel between 1905 and 1912 further accelerated demand for nickel. Nickel had become a vital aerospace material. The discovery of nickel-base superalloys during the 1930s permitted the development of jet aircraft engines and rocket engines during World War II. In the 1980s, soaring sales of mobile telephones, the invention of the laptop computer, and a resurgence of interest in electric vehicles led to the development of the nickel-metal hydride battery. In 2000, Russia, Canada, and Australia were the largest nickel-mining countries. The United States had never been a major source of nickel ore. Japan was the largest nickel-consuming country in the world, followed by the United States and Germany. The United States used 60,300 tons of primary nickel, or about 39% of the 156,000 tons imported, to produce a variety of stainless and alloy steels. Production of superalloys and various nickel-base alloys accounted for another 36% of primary nickel. The remaining 25% was divided largely between batteries, catalysts, coinage, and plating.

Digitized by Google

metal, as opposed to a surface coating of contamination. The principal contaminants in the Oak Ridge nickel are reportedly technetium-99 (a beta emitter with a half-life of 211,000 years) and uranium-235. The nickel is a vestige of the U.S. Government's nuclear weapons programs.

In 1996, DOE awarded a contract to British Nuclear Fuels Ltd. (BNFL) to clean up a defunct gaseous diffusion plant at the Oak Ridge site in the technology park. As part of the contract, BNFL was to decontaminate nickel metal used in the plant operations so that it could be commercially recycled. The DOE plan, however, ran into opposition from several industry and community groups. The American Iron and Steel Institute (AISI), other members of the Metals Industry Recycling Coalition, and the Nickel Development Institute (NiDI) all opposed the release of any decontaminated scrap into the marketplace. On December 21, 1999, NiDI presented a 15-page brief to the U.S. Nuclear Regulatory Commission (NRC) opposing the entry of any "low-level" radioactive nickel scrap into the commercial recycling stream (Nickel Development Institute, 1999a, b). On January 6, 2000, the Specialty Steel Industry of North America issued a similar statement opposing the DOE plan and reaffirming its "zero tolerance" policy toward potentially radioactive scrap metals (Nuclear News, 2000). Because of the strong opposition from the metals industry, the U.S. Secretary of Energy decided on January 12 to prohibit the release of decontaminated nickel scrap into the marketplace until national treatment standards could be developed (U.S. Department of Energy, 2000; Washington Post, 2000). The prohibition also applied to at least 10,000 t of nickel-bearing scrap stored at other DOE facilities (Nuclear News, 2000; U.S. Department of Energy, 2000).

The NRC has begun developing national treatment standards for all volumetrically contaminated materials, including the DOE nickel. Public hearings were held to give concerned citizens an opportunity to participate in developing the new standards.

National Toxicology Program.—The U.S. Department of Health and Human Services was evaluating evidence on the toxicity and carcinogenicity of nickel metal and its alloys. The scientific review was being carried out as part of the National Toxicology Program (NTP). The NTP is funded by the National Institute of Environmental Health Sciences under various Congressional mandates.

From December 13 to 15, 2000, the NTP Board of Scientific Counselors met in Washington, DC, to review the evidence on nickel and seven other nominations. The Board was composed of scientists from the public and private sectors and had been providing primary scientific oversight to the NTP Executive Committee. J&L Specialty Steel Inc., the Specialty Steel Industry of North America, Inco US Inc., the Nickel Producers Environmental Research Association (NiPERA), and the U.S. Food and Drug Administration all made presentations to the Board. The NiPERA representative pointed out that two alloys with the same nickel content can have completely different nickel release rates and, thus, different levels of carcinogenicity. After the presentations, the Board voted to include metallic nickel in the 10th Edition of the Report on Carcinogens. The Board recommended that metallic nickel be treated in the future as a "reasonably anticipated carcinogen." However, the Board voted not to list nickel alloys without more conclusive research and test data.

Environmental Programs.—The Portable Rechargeable Battery Association, a nonprofit trade association comprised of about 90 manufacturers, distributors, assemblers, users, and sellers of small rechargeable batteries, continued to expand its nationwide battery collection and recycling system. The nonprofit, public service recycling program was being administered by Rechargeable Battery Recycling Corp. (RBRC) of Atlanta, GA. The RBRC was supported by more than 285 manufacturer/marketer licensees and a network of 26,000 collection locations across the United States and Canada. The program was made possible by the passage of "The Mercury-Containing and Rechargeable Battery Management Act" (Public Law 104-142) in 1996. The bulk of the spent nickel-cadmium (NiCd) and nickel-metal hydride (NiMH) batteries was being shipped to a pyrometallurgical reclamation facility at Ellwood City, PA. The facility was operated by the International Metals Reclamation Co. Inc. (Inmetco), a subsidiary of Inco Ltd.

New Coinage.—The European Union (EU) and the United States were in the process of issuing new coinage. The two Governments, however, have taken different positions with respect to nickel. The EU has limited nickel in its new coinage to minimize the potential risk of hypersensitive members of the public contracting nickel dermatitis. The U.S. Mint continued to use the cupronickel cladding previously in circulation and apparently has received few complaints about the cladding causing nickel dermatitis.

Commemorative Quarters.—The U.S. Mint produced 6.47 billion quarters (25-cent coins) in 2000, up from 4.43 billion in 1999. The cupronickel-cladded coins were part of the popular 50 State Quarters™ Program launched in December 1998. Between 40 and 60 billion quarters will have been minted when the program ends in 2008. Each State was being honored with its own coin showing George Washington on the obverse (front) and a unique statehood design on the reverse. The five States honored in 2000 were Massachusetts, Maryland, South Carolina, New Hampshire, and Virginia (in order of minting). Since each coin weighs 5.67 grams and contains 8.33% Ni, the total quantity of nickel ending up in the five commemoratives released in 2000 was about 3,060 t.

The U.S. Mint also began releasing the new Golden Dollar coin in March. The dollar coin has an overall composition of 88.5% copper (Cu), 6.0% zinc, 3.5% manganese, and 2.0% Ni.

Euro Coinage.—The European Monetary Union (EMU) was scheduled to have its new euro coinage in circulation by January 1, 2002. After July 1, 2002, coins of the individual member States would no longer be legal tender and were to be scrapped. Because of health considerations, the EMU was using a nickel-free alloy called Nordic Gold for the 10-, 20-, and 50-eurocent pieces and copper-covered steel for the 1-, 2-, and 5-eurocent pieces (Outokumpu Oyj, 1998b). Only the 1- and 2-euro coins contained nickel (Outokumpu Oyj, 1998a). EuroCoin AG, a group of companies within Vereinigte Deutsche Nickel-Werke AG, was one of several contractors making blanks for the German mint. Since 1998, the participating mints have built up huge stockpiles of the new coins at undisclosed locations throughout the EU in anticipation of the 2002 exchange period. The old national coins—many of which contain significant nickel—will be defaced and stockpiled until they can be melted down by contractors into remelt alloys.

National Defense Stockpile.—On June 10, 1999, the U.S. Government sold the last of the nickel in the National Defense Stockpile.

Digitized by Google

Production

Primary Production.—The United States did not produce any primary nickel in 2000. The Glenbrook Nickel Co. was in the process of decommissioning its mining and smelting complex at Riddle, OR. All of the electric arc furnaces have been dismantled and scrapped. The calciner has been moved to another location and will not be used for ferronickel production. Glenbrook, a subsidiary of Teck Cominco Ltd., permanently closed the smelter in March 1998 after the world ferronickel price fell below $6,000 per metric ton ($2.72 per pound) of contained nickel. The recent startup of a greenfield ferronickel operation in Venezuela and the expansion of existing capacity in Colombia, Indonesia, and New Caledonia have discouraged potential ferronickel producers from building facilities elsewhere in the Western United States.

Secondary Production.—Inmetco continued to produce nickel-chromium-iron remelt alloy at its metals recovery facility in Ellwood City, PA. The facility was set up in 1978 to reclaim chromium and nickel from wastes generated by the stainless steel industry. Because of subsequent improvements to the facility, Inmetco can accept a broad spectrum of other recyclable nickel- and/or chromium-bearing wastes, including filter cakes, plating solutions and sludges, catalysts, refractory brick, and spent batteries (Barozzi, 1997).

Inmetco is the only facility in North America that can thermally recover cadmium from NiCd batteries. The cadmium circuit employs a technology that the U.S. Environmental Protection Agency (EPA) has determined to be the best demonstrated available technology for cadmium reclamation. The RBRC program has been encouraging consumers to return their spent NiCd and NiMH batteries to commercial outlets where they are stockpiled and eventually shipped to Ellwood City. The small rechargeable cells are used in a variety of devices, including cellular telephones, transceivers, portable power tools and appliances, medical equipment, and emergency lighting systems. Inmetco also reclaims large industrial cells that are used by railroads, electric utilities, the military, and telecommunication companies for backup power. An estimated 1,600 t of NiCd batteries were collected in the United States and Canada in 2000. Although the tonnage of nickel-based batteries being recycled has increased dramatically since 1996, a significant number still end up in landfills. The RBRC is hoping that future improvements in its program will significantly reduce the tonnage being landfilled.

Byproduct Production.—Limited quantities of nickel were recovered at some copper and precious-metals refineries and at a few plants that reclaim spent catalysts.

The Stillwater Mining Co. has been mining platinum-group metals (PGM) and gold since 1986 from the Stillwater Complex at Nye in Montana's Beartooth Mountains. The ore is associated with the 45-kilometer (km) long J-M Reef. Concentrates from the Stillwater Mine were being trucked to the company's smelting and refining complex at Columbus, MT, where a filter cake containing approximately 60% palladium and platinum was being produced. In 2000, the refinery also produced a byproduct nickel-cobalt solution, which was trucked to Canada where the two metals were recovered. Other byproducts were copper, rhodium, selenium, silver, and tellurium (Stillwater Mining Co., 2001a, p. 18-21; b, p. 3-10).

Stillwater was in the process of expanding the Columbus smelter and has begun construction of a centralized concentrate sampling and drying facility. A second top blown rotary converter was scheduled to come on-stream in late 2001. The expansion was needed to accommodate concentrates from the new East Boulder Mine under development in the western half of the J-M Reef. Several improvements also were made to the refinery in 2000. Copper, selenium, and tellurium are now being recovered on-site by pressure leaching. After removal of the selenium and tellurium, the copper-rich solution is fed to an electrowinning circuit. A nickel sulfate crystallizer circuit, still in the final stage of construction at yearend, became operational in mid-2001. The new crystallizer circuit allows the company to ship its nickel sulfate byproduct as a solid rather than a liquid, minimizing environmental risks and reducing shipping costs.

The Nye mill processed a total of 686,000 t of ore in 2000, with a mill head grade of 20 grams per ton (g/t) of palladium plus platinum. All of the ore came from the Stillwater Mine at the eastern end of the reef. Development of the East Boulder Mine near Big Timber has been underway since mid-1998. The first of two tunnel boring machines intersected the J-M Reef on June 25, 2000. The second boring machine reached the reef on August 24. The East Boulder Mine was scheduled to begin production in 2002 (Stillwater Mining Co., 2001a, p. 2-17).

Spent catalysts are another U.S. source of byproduct nickel. In early 2000, CS Metals of Louisiana, LLC commissioned a spent catalyst reclamation facility on the Mississippi River at Convent, LA. The plant was designed to recover vanadium oxide and molybdenum oxide from spent catalysts used in oil refining and petrochemical operations. The facility also produces a nickel-cobalt byproduct. CS Metals is a joint venture of Strategic Minerals Corp. (Danbury, CT) and CRI International Inc. (Houston, TX), a wholly owned member of the Royal Dutch/Shell Group of companies. The fully permitted plant is in the Baton Rouge/New Orleans refining corridor and uses a patented hydrometallurgical process that produces no solid waste (Strategic Minerals Corp., 1999).

Gulf Chemical and Metallurgical Corp. of Freeport, TX, also processes spent catalysts. The Freeport facility can treat nickel/molybdenum and cobalt/molybdenum hydrotreating catalysts with or without vanadium present. The principal products are oxides of molybdenum and vanadium, fused alumina, and a crude nickel-cobalt alloy byproduct. The nickel-cobalt alloy is produced in an electric furnace and available for sale to nickel refineries. Several of the metals recovered from the spent catalysts are used to manufacture fresh hydrotreating catalyst.

Encycle/Texas, Inc. of Corpus Christi, TX, and U.S. Filter Recovery Services, Inc. of Roseville, MN, have been recovering limited amounts of nickel from electronic scrap and electroplating sludge. Encycle, a wholly owned subsidiary of ASARCO Inc., is now using an innovative electrowinning process to fully reclaim metals from wastes brought to the facility. U.S. Filter recently launched an EPA-approved pilot program that uses ion exchange resins to treat waste waters at electroplating operations.

Consumption

In 2000, demand for primary nickel in the Western World was estimated to have reached an alltime high of 1,029,000 t, surpassing the previous record of 1,004,000 t (revised) set in

Digitized by Google

1999 (International Nickel Study Group, 2001b, p. 3-17). U.S. apparent consumption of primary nickel was 147,000 t, or about 14% of Western demand. U.S. industry consumed an additional 84,000 t of nickel in scrap. Within the United States, the share of primary nickel consumed in the production of stainless and alloy steels fell from 44% in 1999 to 39% in 2000. The drop was attributed to higher prices for primary nickel, the increased availability of scrap, and increased demand for superalloys and other nickel-base alloys. The estimated value of apparent primary consumption in the United States in 2000 was $1.27 billion. Even though consumption declined slightly due to increased prices for primary nickel, the $1.27 billion figure was 51% higher than that of 1999.

Stainless Steel and Low-Alloy Steels.—In 2000, the United States and world demand for nickel continued to be driven by the stainless steel industry. Stainless steel producers accounted for 33% of primary nickel demand in the United States and more than 60% of primary demand in the world. The percentage for the United States was lower because its stainless steel producers operated with higher scrap ratios than some of its foreign competitors.

Production of raw stainless steel in Western countries has doubled in the past 14 years, growing to 17.28 million metric tons (Mt) in 1999 from 7.92 Mt in 1985 (Inco Ltd., 2000f, p. 3-25). Utilization of stainless melt capacity in the Western World has climbed from an estimated 74% in 1996 to 87% in 2000. Because of the high utilization rate, additional melt capacity will have to be brought on-stream by 2005 to accommodate the projected growth in demand for stainless. Between 2002 and 2005, additional capacity is expected to start up in the EU, the Republic of Korea, Taiwan, and the United States. In the interim, reduced growth in demand in East Asia and other overseas markets since 1997 has encouraged foreign stainless steel producers to increase their exports to the United States. Total U.S. imports of stainless steel mill products have grown by 35% since 1996, but domestic production has risen by only 17%.

Production of raw stainless and heat-resisting steel in the United States totaled 2.19 Mt in 2000, almost the same tonnage as in 1999. The tonnage was the highest on record, even higher than that of 1974 when the EPA first required automobiles to have emission control systems. Nickel-bearing grades accounted for 1.24 Mt, or 56% of the total stainless production for 2000 (American Iron and Steel Institute, 2001b). Net shipments of all types of stainless totaled 1.93 Mt, an 11-year high (American Iron and Steel Institute, 2001a, p. 26-29). Shipments of sheets and strip increased 4% to 1.53 Mt, breaking the previous record of 1.47 Mt set in 1999. Shipments of plate, the next largest category, were 188,000 t, or 2% less than that of 1999. Although U.S. stainless steel production and net shipments were practically unchanged from 1999 levels, stainless steel imports increased 6% to 1.07 Mt.

North American Stainless, a subsidiary of Acerinox SA (Madrid, Spain), was building a melt shop at its steel rolling operations in Ghent, KY. The new melt shop was expected to be a major consumer of primary nickel and stainless steel scrap. The facility is designed to produce about 800,000 metric tons per year (t/yr) of hot metal and should be operational by yearend 2001.

Superalloys and Related Nickel-Base Alloys.—About 30% of the primary nickel consumed in the United States was used to make high-performance superalloys and related nickel-base alloys for the aerospace, electric power, and petrochemical industries. U.S. production of nickel-base alloys was up from 1999 because of a strengthening of sales to aircraft manufacturers and manufacturers of turbines for land-based powerplants.

Demand for superalloys is partially reflected in the production backlog and new orders for jet aircraft. Turbine blades, discs, and other critical parts of jet engines are fabricated from superalloys. In 2000, the U.S. aerospace industry earned $9.4 billion on sales of $144 billion—the second highest profits on record (Napier, 2000). Total sales were 4.9% less than those of 1999, when profits peaked at $10.2 billion. The U.S. Government accounted for only 46% of domestic aerospace products and services compared with 70% a decade ago (Napier, 2000). Boeing Co. and its McDonnell Douglas Corp. subsidiary increased their backlog of orders for civil jet transports. A total of 585 net orders for large civil jet transports was received in 2000, compared with 346 in 1999 (Aerospace Industries Association of America, Inc., 2001). Between 1999 and 2000, actual shipments decreased, falling from 620 aircrafts to 485. On December 31, 2000, Boeing had a backlog of 1,612 aircrafts, up from 1,512 at yearend 1999.

Mergers, Acquisitions, and Closures.—The specialty steel industry of the United States continued to restructure in the face of growing imports of stainless steel. U.S. superalloy producers, which have close ties to some of the specialty steel producers, also restructured. The principal force driving the mergers and acquisitions has been the financial synergies created by the integration of similar specialty metals operations.

On November 29, 1999, the management of Allegheny Teledyne Inc. completed its reconfiguration of the company. Only operating units involved in the production and marketing of specialty materials were retained. After the consumer-oriented units were spun off, Allegheny Teledyne changed its name to Allegheny Technologies Inc. The retained units had combined sales of $2.46 billion in 2000, up from $2.30 billion in 1999. The aerospace, automotive, and electrical energy markets accounted for 17%, 13%, and 12%, respectively, of sales. Allegheny Technologies also supplied advanced materials, nickel-based alloys, titanium alloys, and specialty steels to the oil and gas industry for use in drill holes, drilling rigs, and refining plants (Allegheny Technologies Inc., 2001, p. 1-15).

In November 1999, Allegheny Ludlum Corp., the company's specialty steel unit, offered Bethlehem Steel Corp. $20.5 million in cash for its closed stainless steel sheet and strip mill at Washington, PA. Bethlehem accepted and the sale was completed on December 22, 1999. Allegheny Ludlum announced that it would restart the plant's Sendzimir mills together with its annealing and pickling lines (Allegheny Technologies Inc., 1999a, b).

In June 2000, Slater Steel Inc. of Mississauga, Ontario, purchased two Canadian specialty steel operations from Atlas Steels Inc. for C$122 million in cash and the assumption of long-term debt of about C$16 million. The acquisition of Atlas Specialty Steels and Atlas Stainless Steels was finalized on August 1. Shortly afterward, Slater launched a long-term program designed to integrate its U.S. and Canadian specialty steel operations with those of the two former Atlas subsidiaries (Slater Steel Inc., 2000a, b, c). The newly consolidated company now owns and operates the following five minimills in North America:

Digitized by Google

(1) the Fort Wayne Specialty Alloys division in Indiana—a leading producer of stainless steel bar products and the only producer of stainless steel angle in North America;
(2) the Hamilton Specialty Bar division at Hamilton, Ontario—a producer of alloy steel bar and grinding balls which Slater owned prior to the acquisition;
(3) the Atlas Specialty Steels complex at Welland, Ontario;
(4) Atlas Stainless Steels—a stainless steel strip, sheet, and plate operation at Tracy, Quebec; and
(5) Sorel Forge Inc.—a producer of carbon, alloy and stainless steel forgings at Sorel, Quebec, which Slater owned prior to the acquisition.

On August 7, Slater announced that it would close its melt shop at Fort Wayne, IN, in early 2001. The closure would directly affect about 90 employees. Slater was planning to consolidate melting operations at its newly acquired facilities in Welland, Ontario. The Welland melt shop was newer and had significantly more capacity than the Fort Wayne shop. Modernizing the Fort Wayne melt shop would have cost an estimated $30 million (Slater Steel Inc., 2000c). Slater's management believed that the consolidation would make the company more competitive and help ward off growing imports of stainless steel into North America. (See Foreign Trade.)

Advanced Castings and Forgings Industry.—Nickel is used in a variety of brass, stainless steel, and superalloy castings. Nickel also is added to gray-iron castings to toughen the iron, promote graphitization, and improve machinability. The U.S. castings industry shipped an estimated 1.3 Mt of steel castings and 2.5 Mt of nonferrous castings in 1999. Iron castings were about 9.4 Mt. The U.S. foundry industry has consolidated dramatically over the past 40 years. The number of foundries in North America has declined from approximately 6,000 in the 1960s to 3,000 in 2000. Since 1985, Caterpillar Inc., Deere and Co., Gardner Denver Inc., General Electric Co., General Motors Corp. (GM), Siemens Westinghouse Power Corp., and several other major manufacturers of machinery or vehicles have closed one or more of their in-house foundries. In 1999, there were only 400 steel foundries and 700 iron foundries in the United States. At the same time, capacity utilization has increased from 45% to 85%. Cast components are becoming increasingly complex, especially those going to the aerospace and power generation sectors (Atchison Casting Corp., 2000, p. 6-8; Atchison Casting Corp., 2001 inside front cover and p. 1-18).

On June 20, Alcoa Inc. completed its acquisition of Howmet International Inc. Howmet is the largest manufacturer of investment cast turbine engine components in the world and a significant consumer of nickel. Many of the advanced superalloy castings produced by the company are incorporated into jet aircraft engines or industrial gas turbines (Alcoa, 2000c). Many of the nickel-base and other high-temperature alloys used as starting material are produced at the company's metallurgical complex in Dover, NJ. Alloy production from the Dover facility supports several casting plants in the United States, Europe, and Japan. Howmet's corporate headquarters are in Greenwich, CT. The purchase strengthened Alcoa's ties to the U.S. automotive industry and was expected to bring Alcoa closer to Airbus Industrie S.A.S. because of Howmet's business in both new-generation and after-market jet engine components. The purchase also provided Alcoa with an entry into the fast-growing industrial gas turbine market.

On April 18, Alcoa made a cash tender offer of $20 per share to Howmet shareholders after direct negotiations with Howmet's Board of Directors stalled. At that time, about 15.4 million shares of Howmet common stock were outstanding. On June 2, Alcoa raised its offer to $21 per share and ended up paying about $324 million for the stock (Alcoa Inc., 2000a). The Howmet acquisition came less than a month after Alcoa acquired Howmet's parent—Cordant Technologies, Inc. of Salt Lake City, UT. The acquisition of Cordant was completed on May 25 after Alcoa received clearance from antitrust authorities in the EU and the United States (Alcoa Inc., 2000b). Cordant owned 84.7% of Howmet's outstanding shares prior to the May transaction (Alcoa Inc. and Cordant Technologies, Inc., 2000).

On January 12, 2000, Precision Castparts Corp. (PCC) of Portland, OR, completed its acquisition of the Wyman-Gordon Co. The acquisition was made through a cash tender valued at $731 million (Precision Castparts Corp., 2000, p. 1-5, 25-28). The acquisition, which ended up costing $784 million, broadened PCC's capabilities in the aerospace industry and also gave the Oregon-based company a niche in the aluminum castings business. Wyman-Gordon is a leading producer of forgings for the aerospace, industrial gas turbine (IGT), and energy markets. PCC makes superalloy investment castings for the aerospace, power generation, and general industrial sectors. Many of these castings contain significant nickel. PCC also makes investment castings for automotive and medical applications. The acquisition offered considerable synergies, cost reduction, and manufacturing improvements. PCC now has a much stronger presence in the booming IGT market. For the time being, Wyman-Gordon will operate as a separate Precision Castparts business while maintaining its own forging business identity.

During the year, PCC also acquired Drop Dies & Forgings Co. of Cleveland, OH, and UEF Aerospace of Lincoln, England. Drop Dies & Forgings specializes in the production of high-quality forgings from difficult-to-forge metals, including aluminum, titanium, and high-temperature nickel superalloys. UEF Aerospace, a unit of the British automotive specialist United Engineering Forgings, Ltd., was made a division of Wyman-Gordon. UEF Aerospace (renamed Wyman-Gordon Lincoln Ltd.) produces forged engine discs, engine shafts, and airframe and landing gear components, primarily for British jet engine maker Rolls-Royce plc (Precision Castparts Corp., 2001, p. 1-3).

Nickel-Based Batteries.—U.S. demand for nickel in rechargeable batteries may now exceed U.S. demand for several other important end uses, such as copper-nickel alloys and coinage.

Battery Manufacturing.—Texaco Ovonic Battery Systems LLC (formerly GM Ovonic LLC) manufactures NiMH batteries for electric, hybrid electric, and fuel cell electric vehicles. The main plant is at Kettering, OH. Some key battery components, though, are produced in development facilities operated in Troy, MI, by Ovonic Battery, Inc.—one of Texaco Ovonic's parents. Ovonic Battery and GM formed the joint venture in 1994 to manufacture electric vehicle (EV) batteries using proprietary NiMH technology developed by Ovonic Battery. Prior to 2000, GM had a 60% interest in the joint venture; Ovonic Battery, 40%.

On May 1, 2000, Texaco Inc. purchased a 20% equity interest in Energy Conversion Devices, Inc. (ECD) of Troy, MI, for $67.4 million. ECD, in turn, has a 91.4% interest in Ovonic Battery. ECD is a leading developer of advanced energy

Digitized by Google

technologies and is perhaps best known for its patents on the NiMH battery (Texaco Inc. and Energy Conversion Devices, Inc.; 2000 Energy Conversion Devices, Inc., 2001, p. 7-18). In early October, ECD, GM, and Texaco restructured GM Ovonic. Texaco took over GM's interests in the Kettering operation and is now an equal partner with Ovonic Battery. GM has since designated Texaco Ovonic as a preferred supplier for its NiMH battery requirements and is collaborating on a development program with the battery manufacturer. The sale of GM's interests to Texaco was completed on July17, 2001.

Texaco formed two other joint ventures with ECD in 2000 that were aimed at further developing and eventually commercializing fuel cells for automobile propulsion. (See Current Research and Technology.)

Electric and Hybrid Electric Vehicles.—Although EVs were being commercially manufactured in the EU, Japan, and the United States, production and sales were still limited. Fewer than 6% of the 2002-model automobiles and trucks arriving at U.S. dealerships were able to get more than 7.8 liters per 100 kilometers (L/100km) or about 30 miles per gallon (mpg). Of the 491 passenger car models evaluated in combined city and highway driving by the EPA in 2001, the average fuel economy was only 9.84 L/100km or 23.9 mpg. The best achievers were two hybrid gas- and electric-powered vehicles. The hybrids—the two-seat Honda Insight coupe and the five-seat Toyota Prius sedan—were rated at 3.7 L/100km (or 64 mpg) and 4.9 L/100km (or 48 mpg), respectively (Heilprin, 2001).

At yearend 2000, at least six EV models equipped with NiMH batteries were being sold or leased in the United States. A total of 1,270 battery electric light-duty passenger vehicles and trucks were reported leased or sold in 1999. A significant number of the 1,270 vehicles, especially trucks, used lead-acid batteries as a cost savings measure. The new Generation I NiMH battery made by Texaco Ovonic can store twice the energy of a conventional lead-acid battery for the same weight and volume. At yearend 2000, more than 4,000 EVs were on U.S. highways. Sales of hybrid electric vehicles (HEVs) were growing at a much faster rate—4,402 Honda Insight coupes and 8,052 Toyota Prius sedans were sold or leased between October 1999 and March 2001 (Electric Vehicle Association of the Americas, 2001).

On December 22, 1999, the United States Postal Service ordered 500 electric mail delivery vehicles from the Ford Motor Co. and its partner, Baker Electromotive, Inc., of Rome, NY. The postal service had an option to order 5,500 additional vehicles. The design of the delivery vehicle was based largely on Ford's Ranger EV. Production began in the fall of 2000 and was to continue through 2001 at the rate of 45 vehicles per month. The purchase will increase the Federal electric vehicle fleet by more than 400% (Ford Motor Co. and Baker Electromotive, 1999).

Stocks

On December 31, 2000, U.S. consumer stocks of primary nickel (cathode, pellets, briquets, powder, etc.) totaled 6,490 t—34% greater than the 4,850 t (revised) at yearend 1999. Stocks in London Metal Exchange (LME) warehouses worldwide, in contrast, plummeted 79% during 2000 to 9,678 t. LME stocks at yearend 1999 and 1998 were 46,962 t and 65,964 t, respectively. Data collected by the International Nickel Study Group indicated that, at yearend 2000, world nickel producers (excluding those in Austria, China, the former Yugoslavia, and the Ural area of Russia) had approximately 87,500 t of nickel in primary products in stock (International Nickel Study Group, 2001b, p. 10-11).

Prices

The monthly average cash price for 99.8% pure metal on the LME peaked in March at $10,280 per metric ton ($4.663 per pound) and then gradually declined throughout the rest of the year. (See figure 1.) By yearend, the monthly average price had fallen to $7,314 per ton ($3.318 per pound). The cash prices for January and February 2001 were even lower—$6,995 per ton ($3.173 per pound) and $6,524 per ton ($2.959 per pound), respectively. The weakening of prices was attributed primarily to the economic slowdown in the United States and parts of East Asia. The end of strikes at Canadian nickel mines, the ramping up of three new pressure-acid-leach complexes in Australia, and the startup of the Loma de Niquel ferronickel operation in Venezuela also helped to lower prices in the second half of 2000 by firming up Western World supplies. The supply increase was partially offset by a strengthening of demand for stainless steel in East Asia, which kept nickel prices from collapsing in the fourth quarter. Japanese production of austenitic stainless steel increased from 1.84 Mt gross weight in 1999 to 2.07 Mt in 2000, an increase of 12% (International Nickel Study Group, 2001b, p. 18). The East Asian recovery also led to increases in stainless steel production in the Republic of Korea and Taiwan (World Bureau of Metal Statistics, 2000, p. 8).

In 2000, the last weekly price (for the 4 days ending December 29) was $7,158 per ton ($3.247 per pound). The average annual price was $8,638 per ton ($3.918 per pound). The annual price was 44% higher than the 1999 average of $6,011 per ton ($2.727 per pound).

Foreign Trade

U.S. net import reliance as a percentage of apparent consumption was 56% in 2000—significantly less than the 63% for 1999 because of increased scrap usage. Imports accounted for 100% of primary supply. The United States imported 156,000 t of primary nickel in 2000, 12% more than the 139,000 t for 1999. Class I materials accounted for 86% of total primary imports received. Canada, as usual, supplied most of the primary imports. The second largest source was Russia, recapturing the position from Norway. RAO Norilsk Nickel has become an important source of nickel metal for the United States since the dissolution of the Soviet Union. Almost all of the Norwegian nickel was produced from foreign matte processed at Falconbridge Ltd.'s refinery in Kristiansand. Australia was in fourth place, with shipments from Murrin Murrin and the two other new pressure-acid leach plants near Kalgoorlie entering the United States for the first time. (See Australia.)

Prices for nickel-bearing scrap tracked those for primary nickel, decreasing almost continuously during the second half of 2000 because of the deteriorating economic outlook in the EU, the United States, and parts of East Asia. Increased exports of Russian scrap added to the downward pressure on primary and secondary prices. Most of the Russian scrap was consumed in

Digitized by Google

the EU and did not enter the U.S. market. The EU imported 344,000 t (gross weight) of stainless steel scrap from Russia in 2000, the second highest tonnage in the past 5 years and 36% more than the 253,000 t in 1999 (International Nickel Study Group, 2001b, p. 64-65). U.S. exports of stainless steel scrap to the EU totaled 55,300 t (gross weight), up 59% from 1999 levels.

U.S. producers of specialty steels concerned about the country's continuing high level of specialty steel imports filed additional antidumping and countervailing duty petitions with the U.S. Department of Commerce and the U.S. International Trade Commission (ITC). In 2000, specialty steel imports reached a record 811,000 t (gross weight). Stainless steel accounted for 628,000 t, or 77% of the 811,000 t total. Electrical steel constituted 14%, and tool steel, 9% (Specialty Steel Industry of North America, 2001). Imports had slackened slightly in 1999 to 757,000 t because of the ongoing trade investigations, but began rising again in the first half of 2000, outpacing growth in U.S. consumption (Specialty Steel Industry of North America, 2000). Japan, the Republic of Korea, and Taiwan were cited in several of the U.S. producers' petitions. In 2000, total imports of all stainless steel long products (bar, rod and wire) captured 52% of the U.S. market.

On August 18, 2000, Slater Steels Corp. (the U.S. subsidiary of Slater) and the United Steelworkers of America filed an antidumping petition with the U.S. Government. The petition alleged that Japanese, South Korean, and Spanish producers were selling stainless steel angle in the United States at less than fair value. Stainless steel angle (a length of steel with a cross section resembling the letter L) is used to reinforce the interiors of stainless steel tanks commonly found in the food, dairy, and chemical processing industries. On September 28, the ITC determined preliminarily in a 6-0 vote that unfair trade practices had indeed injured domestic stainless steel producers. The stainless steel angle case was subsequently referred to the U.S. Department of Commerce for determination of antidumping margins (Slater Steels Corp.., 2000a, b).

World Review

The world's largest nickel producer was Norilsk Nickel, followed by Inco. Other major producers were Billiton plc of the United Kingdom, the Eramet Group of France, Falconbridge Ltd. of Canada, and WMC Ltd. of Australia. The six companies accounted for about 66% of world primary production in 2000. More than 30 medium to small companies supplied the remaining 34%. The nickel industry has become highly competitive as a result of recent corporate alliances and new developments in extractive metallurgy.

In December 2000, Anglo American plc commissioned its mining and smelting complex in Venezuela at Loma de Niquel. The mining giant increased or retained its holdings in several other medium-sized nickel producers. At yearend 2000, Anglo American had interests in the following six producers: Anaconda Nickel Ltd. of Australia (26%), BCL Ltd. of Botswana (23%), Bindura Nickel Corp. Ltd. of Zimbabwe (53.11%), Codemin S.A. of Brazil (90%), Minera Loma de Niquel, C.A. of Venezuela (85.5%), and Tati Nickel Mining Co. (Pty.) Ltd. of Botswana (43.35%). Anglo American also was involved in the Barro Alto Project (Brazil) and the Kabanga Project (Tanzania).

OM Group Inc. (OMG) of Cleveland, OH, has taken a number of steps since 1998 to transform the chemical company into a fully integrated nickel producer. OMG already had chemical production operations in the Congo, France, Germany, Malaysia, Thailand, and the United States before these actions were taken. In April 2000, OMG bought the nickel refinery at Harjavalta, Finland, from Outokumpu Oyj (Juusela, 2000). (See European Union—Finland.) OMG also formed a partnership with Weda Bay Minerals Inc. to evaluate the Halmahera laterite deposits in Indonesia. (See Indonesia.)

Global competition among stainless steel producers intensified in 2000. The increased competition and associated antidumping actions led to at least one key merger. On January 22, 2001, Avesta Sheffield AB and Outokumpu Steel Oyj merged their stainless steel manufacturing operations. The new consolidated company, AvestaPolarit Oyj Abp, became the world's second largest producer of stainless steel slabs. AvestaPolarit now has about 8,900 employees and was expected to have net sales of more than EUR 3.5 billion (about $3.2 billion) in 2001. Key production plants are located in Finland, Sweden, the United Kingdom, and the United States. The company's melt shop facilities in the four countries have a combined stainless steel slab capacity of about 1.7 million metric tons per year (Mt/yr) (Avesta Sheffield AB, 2001; Outokumpu Oyj, 2001; Outokumpu Oyj and Avesta Sheffield AB, 2000).

Avesta Sheffield and Outokumpu announced their intention to merge in September 2000, but first had to obtain approval from antitrust authorities in the European Commission and five foreign governments, including the United States (Avesta Sheffield AB, 2000). The new company is incorporated in Finland and has its head office in Stockholm. The merger had the full support of the Finnish State, which owned 40% of Outokumpu Oyj at the time. Exchanging of shares of Avesta Sheffield for shares of Outokumpu Steel began on December 21, 2000, and continued until February 2, 2001. Outokumpu Steel was renamed AvestaPolarit during the exchange period. The two largest shareholders in AvestaPolarit were Outokumpu Oyj (55.3% equity) and Corus Group plc (23.2%). Outokumpu Oyj agreed to reduce its holdings to 40% within 3 years so that AvestaPolarit's stock would be more liquid.

Outokumpu Steel's Kemi-Tornio complex is the only fully integrated stainless steel production operation in the world, starting with chromite ore and ending with finished stainless steel products. The new company was expecting to spend more than EUR 680 million (about $615 million) on expansion of its Tornio operation. Most of the money was being used to construct a new melt shop and expand rolling capacity (Outokumpu Oyj and Avesta Sheffield AB, 2000; AvestaPolarit Oyj Abp, 2001). The merger allowed Outokumpu Oyj, the parent of Outokumpu Steel, to focus on developing its remaining nonferrous businesses—copper and zinc.

Australia.—Australia is now the third largest nickel producing country in the world and is beginning to rival Canada. Most of the nickel properties under development are in Western Australia. By 2002, nickel production capacity of Western Australia is projected to reach 200,000 t/yr. WMC was still the largest nickel producer in the State, recovering 107,458 t of nickel in sulfide concentrate in calendar year 2000, up from 88,275 t in 1999 (WMC Ltd., 2001b).

Australian Sulfide Operations.—In early 2000, WMC increased production at its operations in Western Australia because of strengthening nickel prices. All three mining

Digitized by Google

operations—Kambalda, Leinster, and Mount Keith—produced more in 2000 than in 1999. The Kambalda Mines showed the biggest gain, with output of concentrate increasing to 19,202 t of contained nickel in 2000 from 11,114 t. Production at the huge Mount Keith Mine northwest of Leinster resumed its upward trend, rising to 47,532 t from 41,208 t. Production at the Leinster Mines increased to 40,724 t from 35,953 t (WMC Ltd., 2001b). WMC's smelter at Kalgoorlie produced 103,000 t of Ni in matte, up from 79,668 t in 1999. During the year, WMC acquired the Yakabindie deposit, 25 km south of Mount Keith. The Yakabindie deposit contains an estimated 292 Mt of resources averaging 0.52% Ni (WMC Limited, 2001a, p. 16-17).

Australian Laterite Projects.—Pressure acid leach (PAL) production capacity continued to grow in Western Australia at a rapid rate. Three nickel laterite mining and processing operations have been commissioned in the Kambalda-Goldfields region since mid-1998—Bulong, Cawse, and Murrin Murrin (Mining Journal, 1999b). Together, the three initially should eventually add about 60,000 t/yr of nickel to world production capacity. By May 2000, however, only Cawse had approached design capacity. The other two continued to experience ramp-up problems.

Murrin Murrin.—Anaconda Nickel Ltd. began producing nickel metal at its new Murrin Murrin refinery in May 1999 (Anaconda Nickel Ltd., 1999d). The metal reportedly had a chemical purity of greater than 99.80% Ni and was being marketed as briquets (Hagopian, 1999). Briquets produced in the fourth quarter of 2000 reportedly averaged 99.93% Ni, 0.026% cobalt (Co), and 0.002% Cu, fully meeting LME specifications (Anaconda Nickel Ltd., 2001).

The development plan originally called for production to be gradually increased during the second half of 1999 to the full Stage I design capacity of 45,000 t/yr of nickel and 3,000 t/yr of cobalt (Anaconda Nickel Ltd., 1999e). Nickel production for 1999 was supposed to have been about 16,000 t (Platt's Metals Week, 1999a, b) but startup problems resulted in an actual output of only 1,000 t. In July 1999, Anaconda began a 100-day campaign to rectify several technical problems that had constrained production. Some of the problems were attributed to design flaws in the flash vessels of the plant's four autoclave systems. The flash vessels have since been converted from bottom entry to top entry. Stainless steel piping in some of the autoclave circuits was unable to withstand the corrosiveness of the acidic solutions and had to be replaced by titanium alloy pipe.

The Murrin Murrin refinery produced about 4,100 t of nickel in the fourth quarter of 2000. The complex is now scheduled to reach the original target of 45,000 t/yr of nickel in the first half of 2002. Anaconda was already preparing to launch Stage II and expand the capacity of Murrin Murrin to 106,000 t/yr of nickel and 7,600 t/yr of cobalt. Stage II would use a process developed in-house instead of the original Sherritt process (Anaconda Nickel Ltd., 2001). The expansion could make Murrin Murrin the largest nickel mine in Australia, surpassing Mount Keith. According to Anaconda officials, the resources of the Murrin Murrin project (including the Abednego property) now total more than 355 Mt of ore grading 0.99% Ni and 0.07% Co.

Mount Margaret Project.—Anaconda also was preparing to develop its Mount Margaret property, 100 km northwest of Murrin Murrin. Test work on the Marshall Pool and Lawlers ore bodies indicates a resource of at least 170 Mt grading 0.78% Ni and 0.045% Co (Anaconda Nickel Ltd., 1999f). Total resources in the Mount Margaret region reportedly exceed 585 Mt and average 0.67% Ni. Drilling was underway to better delineate the resources at Mount Margaret and a feasibility study was in progress.

The proposed centralized Mount Margaret nickel refinery would have an initial design capacity of 63,600 t/yr of nickel. The development of the Murchison properties northeast of Meekatharra would allow the Mount Margaret refinery to be expanded to 130,000 t/yr. The refinery would be fed by two modular PAL plants—one at Marshall Pool and the other at Murchison.

Bulong and Cawse.—Like Murrin Murrin, Bulong and Cawse experienced startup problems associated with the new PAL technology but eventually overcame the bulk of the problems and are now in production. The two also were using solvent extraction technology to separate the cobalt from the nickel. All three, however, had somewhat different circuits.

In March 1999, Preston Resources Ltd. began continuously producing nickel metal at Bulong (Mining Journal, 1999c). Preston was also stockpiling cobalt sulfides (Mining Journal, 1999a), although the Bulong cobalt refinery was still in the final stages of commissioning. The Bulong complex was originally designed to produce 9,000 t/yr of nickel and 700 t/yr of cobalt. In October 1999, Anaconda and Preston agreed to jointly expand Bulong's production capacity and were considering raising the nickel output of the complex to 40,000 t/yr. Anglo American—Anaconda's partner—was reportedly backing Anaconda's involvement. Anaconda agreed to manage Bulong for Preston and review existing work. Anaconda can earn up to a 60% interest in Bulong. Preston's largest shareholder, Resolute Ltd., reportedly agreed to support the joint venture under certain conditions. The expansion feasibility study was scheduled to be completed by August 2001.

The Cawse complex is in the Eastern Goldfields region, 60 km northwest of Kalgoorlie. The complex produced its first cobalt sulfide concentrate, assaying 40% Co, on December 25, 1998, and the first nickel cathode was made on January 20, 1999 (Western Australian Department of Resources Development, 1999). The complex is owned and operated by Centaur Mining and Exploration Ltd. When fully operational, Cawse is expected to produce 8,700 t/yr of nickel and 1,300 t/yr of cobalt.

In November 1999, Anaconda formed a strategic alliance with Centaur Mining to expand the Cawse operation (Anaconda Nickel Ltd., 1999a). Anaconda and Centaur proposed raising the capacity of Cawse to more than 50,000 t/yr. The two companies were expecting to complete an expansion feasibility study by mid-2001. Anaconda was to be responsible for the financing, construction, commissioning, and operation of the expanded plant. Anaconda could earn as much as a 60% interest in Cawse.

Marlborough.—Preston also was preparing to develop the Marlborough laterite deposit on the central Queensland coast, about 75 km northwest of Rockhampton. Marlborough Nickel Pty. Ltd., the project manager, was in the process of securing the permits required for development and construction. Marlborough Nickel is a wholly owned subsidiary of Preston. The proposed hydrometallurgical complex would produce 25,000 t/yr of nickel metal and 2,000 t/yr of cobalt metal. Sufficient resources have been identified to permit the plant to

Digitized by Google

operate for at least 22 years and possibly 100 years. According to company officials, Marlborough has about 210 Mt of resources grading 1.02% Ni and 0.06% Co (Preston Resources Ltd., 1999).

Ravensthorpe Project.—Comet Resources Ltd. (formerly Comet Resources NL) and BHP Billiton plc were preparing to develop the Ravensthorpe nickel property, 150 km from the southern port of Esperance. Comet's latest plan called for the complex to have a design capacity of 35,000 t/yr of nickel metal and 1,400 t/yr of cobalt sulfide (Comet Resources NL, 1999; Comet Resources Ltd., 2000). Construction of the Halleys cut—the proposed initial open pit on Bandalup Hill—was scheduled to begin in early 2001. The first of three pits would have a projected life of 10 to 15 years. Like Marlborough, the ore would be beneficiated before being fed into an autoclave. The beneficiated ore would have a nickel content of 2.0%. The PAL plant would adjoin the ore beneficiation plant.

In November 1999, QNI Pty. Ltd., the Queensland subsidiary of BHP Billiton, paid Comet $22 million for a 40% interest in the project. The proposed Ravensthorpe PAL plant would ship an intermediate nickel and cobalt concentrate to QNI's existing Yabulu plant near Townsville, Queensland (Mining Journal, 1999d). In September 2000, QNI acquired an additional 10% from another venture partner. On March 9, 2001, QNI agreed to purchase Comet's remaining interest in Ravensthorpe for $14.3 million plus the cancellation of its 19.9% interest in Comet (Billiton plc, 2001a).

Processing of Intermediates and Refining.—QNI produced 25,208 t of nickel metal at its Yabulu refinery during fiscal year 1999-2000 (Billiton plc, 2000). Laterite feed for the refinery was being supplied by PT Aneka Tambang (Persero) Tbk. (AnTam) in Indonesia, Hinatuan Mining Corp. in the Philippines, and four mining companies in New Caledonia.

Canada.—Key events of 2000 are summarized in the nickel chapter of the Canadian Minerals Yearbook (McCutcheon, 2001).

Labrador.—Inco Ltd. and its subsidiary Voisey's Bay Nickel Co. Ltd. (VBNCL) remained committed to developing the huge nickel-copper-cobalt deposit at Voisey's Bay. An impasse between Inco and the Provincial Government of Newfoundland and Labrador over the scope of the project continued to delay development (Inco Ltd., 1999). On January 11, 2000, Inco and the Provincial Government mutually agreed to suspend negotiations on the Voisey's Bay Project. Spokespersons for Inco and the Provincial Government were not willing to predict when negotiations might resume.

Inco has decided to recover the nickel using a new hydrometallurgical process developed in-house instead of using flash smelting technology as originally planned. On November 14, 1999, Inco delivered a new development proposal for Voisey's Bay to the Provincial Government (Whyte, 1999). In the proposal, Inco offered to build a hydrometallurgical pilot plant in the Province but did not want to commit to building a full-scale facility until the new process was determined to be technically and economically feasible. The proposed pilot plant and associated research and development program would have cost about $125 million (Inco Ltd., 2000f). Inco also would have spent about $65 million on underground exploration at the mine site.

Despite the impasse, Inco was permitted to push ahead with its surface exploration program. According to Inco, the Voisey's Bay deposit has 32 Mt of proven reserves averaging 2.83% Ni and 1.68% Cu. All of these reserves reportedly can be recovered by open pit mining. In addition to these reserves, geologists have calculated that there are 95 Mt of indicated resources averaging 1.28% Ni and 0.60% Cu plus 14 Mt of inferred resources averaging 0.98% Ni and 0.66% Cu (Inco Ltd., 2001, p. 26-27). The bulk of these resources would have to be recovered using underground mining techniques. A minihydrometallurgical pilot-plant program was scheduled to begin in 2001 at the company's Sheridan Park research center.

Inco was working with the Labrador Inuit Association to establish baseline metal concentrations in meadows and other sensitive areas near the proposed mine site. The baseline environmental data will be used to ensure that metal concentrations do not rise when commercial mining begins.

On December 14, Inco redeemed the Class VBN shares that were issued when Diamond Fields Resources Inc. and the Voisey's Bay deposit were acquired in 1996. Each VBN share was exchanged for C$7.50 in cash and a fraction, 0.45, of an Inco common share purchase warrant. The warrant can be used to purchase one Inco common share for C$30.00 on or before August 21, 2006.

South Voisey's Bay, Labrador.—Donner Minerals Ltd. and its partners had planned to spend C$2.75 million exploring their claims in the South Voisey's Bay (SVB) project area during the 1999 field season. However, on July 6, 1999, Donner announced that the company had been unable to reach an agreement with the Innu Nation, which was still conducting land claims negotiations with the Federal and Provincial Governments. Donner was unwilling to risk a confrontation at its SVB exploration camp and decided to cancel its 1999 exploration program (Donner Minerals Ltd., 1999). Donner kept the exploration program on hold throughout 2000 while it negotiated with the Innu Nation.

Ontario.—The Sudbury region of Ontario, northwest of Lake Nipissing, has been the principal nickel-producing district in Canada since 1883. Inco operates a smelting complex at Copper Cliff, on the western edge of the City of Sudbury. Falconbridge Ltd. has a somewhat smaller smelter near the town of Falconbridge. Concentrates for the two smelters come from a number of underground mines ringing the perimeter of the Sudbury Basin. Ore production at Falconbridge's four Sudbury mines totaled only 1.79 Mt and was down 35% from 2.75 Mt in 1999 because of a prolonged labor strike and the impact of a rockburst in the Fraser Mine. The ore averaged 1.54% Ni and 1.37% Cu (Falconbridge Ltd., 2001, p. 18-19).

Falconbridge and Inco have continued to find additional resources along the basin rim. Inco and two major producers of PGM recently accelerated their exploration efforts in the region. Higher nickel prices, improved PGM fundamentals, and two recent discoveries of nickel-copper sulfides on the southern perimeter of the Sudbury Basin all contributed to the expansion of exploration activities.

Kelly Lake and Totten Deposits.—Inco management was expected to decide in 2001 when the Kelly Lake deposit should be brought into production. The deposit is 2 km south of Copper Cliff and Highway 17 and reportedly is accessible from existing mine workings near Inco's Copper Cliff South Mine.

Inco geologists continued to evaluate a new area of mineralization in and around the Totten Mine, near Worthington on the Canadian Pacific Railway. The mineralization was discovered in late 1999. Subsequent drilling indicated that the

Digitized by Google

Totten deposit has at least 8.4 Mt of resources averaging 1.42% Ni, 1.90% Cu, and 4.7 g/t of PGM (Inco Ltd., 2000d). If the necessary environmental permits can be obtained in 2001, production could begin as early as 2005.

The Kelly Lake and Totten deposits both have average nickel and PGM concentrations higher than those being mined by Inco's Ontario Division. The average ore grade for the Division currently is 1.41% Ni, 1.40% Cu, and 1.8 g/t of PGM. Because of the two new finds, Inco decided to spend $7.7 million in 2000 exploring several high potential targets in the region. This was Inco's highest annual exploration expenditure (in nominal dollars) in Ontario since the 1970s.

Other Nickel-PGM Targets.—Anglo American Platinum Corp. Ltd. of Johannesburg, South Africa, has teamed up with Pacific Northwest Capital Corp. (PNWC) of Vancouver, BC, to evaluate the River Valley mafic intrusion, 50 km east of Sudbury. The intrusion is a layered gabbro-anorthosite complex, with elevated PGM values near its contact with the country rock. Mustang Minerals Corp. of Toronto, ON, and Impala Platinum Corp. of Johannesburg, South Africa, have joined forces to explore parts of the intrusion adjoining PNWC's license area (Mining Journal, 2000c).

Mustang also was exploring a second gabbro-anorthosite complex at East Bull Lake, 80 km west of Sudbury. Again, PGM values appear to be enriched at the margins of the intrusion (Mining Journal, 2000a).

Quebec.—Exploration activities have increased dramatically in parts of Quebec since the discovery of the Voisey's Bay deposit in neighboring Labrador and the startup of Falconbridge's Raglan Mine on the Ungava Peninsula.

The Raglan mining and milling complex completed its second full year of operation. The new nickel-copper mine is in the Nunavik region of northern Quebec—near Katinniq, at the tip of the Ungava Peninsula. Falconbridge spent C$25 million in 2000 to increase annual milling capacity from 800,000 t of ore to 1 Mt. In 2000, Raglan recovered 936,000 t of ore averaging 2.94% Ni and 0.86% Cu. This equated to a mine production of 23,089 t of nickel in concentrate. The nickel concentrate also contained 6,308 t of copper and 289 t of cobalt (Falconbridge Ltd., 2001, p. 18-19).

Falconbridge was hoping to eventually raise production capacity to 30,000 t of nickel in concentrate. At yearend 2000, Raglan had 19.5 Mt of proven and probable reserves, averaging 2.85 % Ni and 0.78% Cu. In addition to the reserves, Raglan had 2.74 Mt of indicated resources averaging 1.86% Ni and 0.69% Cu (Falconbridge Ltd., 2001, p. 13).

Manitoba.—Inco's Manitoba Division produced about 45,000 t of nickel, up 33% from 34,000 t in 1999 (McCutcheon, 2001). There were two principal mines—the Birchtree and Thompson. Inco has decided to deepen the Birchtree over the next 5 years and has begun resurveying the entire Thompson Nickel Belt (Inco Ltd., 2000b).

Canmine Resources Corp. continued to evaluate 2,000 square kilometers (km^2) of claims northeast and west of the Thompson Belt (Canmine Resources Corp., 1999b). In early 2000, Canmine transferred its interests in the BINCO project to a wholly owned subsidiary named BINCO Resources Corp. In March 1999, Canmine obtained 21-year renewable surface and mineral right leases on its Maskwa property in Nopiming Provincial Park from the Province of Manitoba (Canmine Resources Corp., 1999a).

Alberta.—Sherritt International Corp. continued to improve operations at its Fort Saskatchewan refinery. Finished nickel production was 28,070 t, slightly below the record of 28,643 t set in 1999 (Sherritt International Corp., 2001, p. 7). The bulk of the feedstock—nickel-cobalt sulfide precipitate—came from Metals Enterprise, a mining and concentrating operation at Moa in Cuba. Metals Enterprise is a 50-50 joint venture between Sherritt and the Government of Cuba.

China.—Recent advances in nickel and rare-earth electrochemistries have spurred several joint battery manufacturing projects in mainland China and Taiwan.

Evercel, Inc. of Danbury, CT, and Xiamen Three Circles Battery Co. have formed a joint venture to mass produce rechargeable nickel-zinc batteries in Fujian Province, China. The nickel-zinc batteries were being used to power bicycles, scooters, and small automobiles. The joint venture developed from a licensing agreement signed in February 1998 between Energy Research Corp. (ERC) and its two partners—the Formosa Plastics Group of Taiwan and the City of Xiamen, China (Energy Research Corp., 1998). Evercel was spun off from ERC on February 22, 1999, and shortly after opened its corporate headquarters along with a pilot production line at Danbury. The pilot production facility was producing sample quantities of the new batteries for field testing by prospective customers (Evercel, Inc., 1999a).

In August 1999, the joint venture, Xiamen Three Circles - ERC Battery Corp. Ltd., began manufacturing nickel-zinc batteries for electric bicycles at its brand-new facilities in Xiamen (Evercel, Inc., 1999b). The joint venture's first production order came from the Xiamen Bicycle Co. The Chinese post office department was using the electric bicycles to deliver mail. Evercel also assumed responsibility for the original licensing agreement with the Xiamen City government and Formosa Plastics. The original agreement allows Xiamen City and Formosa Plastics to jointly manufacture patented nickel-zinc batteries for electric and hybrid automobiles. Xiamen City's automotive company produces 30,000 conventional cars and trucks annually (Energy Research Corp., 1997).

Nan Ya Plastics Group, a Formosa Plastics subsidiary, has been developing new markets for nickel-zinc batteries on Taiwan. Xiamen Three Circles-ERC was hoping to sell a significant part of its production to Taiwanese electric scooter manufacturers. Taiwanese electric scooters are currently powered by lead-acid batteries. Comparison road testing of an Evercel scooter battery with an equivalent lead-acid battery was carried out by Taiwan Sanyang Industry Co., Ltd., one of the island's leading scooter manufacturers. The total life distance of the nickel-zinc-powered scooter was reportedly twice that of the lead-acid alternative (Evercel, Inc., 1999c). Recent environmental regulations adopted by the Taiwan Authorities require that, starting in 2000, 2% of the scooters manufactured on the island must be electrically powered. Electric scooter manufacturers were expecting to sell 33,000 battery packs in 2000.

On August 26, 1999, ECD and its subsidiary, Ovonic Battery, signed a cooperation and licensing agreement with Rare Earth High-Tech Co. Ltd. of Baotou. Rare Earth High-Tech is the largest producer of rare-earth elements in China and has mining and extraction operations in the Nei Mongol Autonomous Region. The company is a subsidiary of Baotou Iron and Steel Ltd. Rare Earth High-Tech and Ovonic Battery have agreed to jointly produce key materials for NiMH batteries. Proprietary

Digitized by Google

rare-earth alloys are used as anodes in certain types of NiMH batteries. Several joint projects were planned, including production of hydrogen storage alloy powders, production of advanced nickel-hydroxide materials, and development of battery production equipment (Energy Conversion Devices, Inc., 1999).

Colombia.—On January 1, 2001, Billiton plc commissioned a second ferronickel production line at its Cerro Matoso S.A. (CMSA) subsidiary in northwestern Colombia. The commissioning marked the turning point in a 5-year project to expand operations and reduce production bottlenecks at the mining and smelting complex near Montelibano. Startup was achieved 3 months ahead of schedule, while costs were kept below the $353 million budgeted. Production on the second line was to be gradually increased over the next 18 months until the design capacity of 27,000 t/yr of contained nickel was reached. When the ramp-up is completed in July 2002, the two lines will have a combined production capacity of 55,000 t/yr of Ni in ferronickel (Billiton plc, 2001b). Each line has its own ore dryer, kiln, and smelting furnace, so that the ferronickel plant can now be operated continuously. The expanded plant reportedly has been designed so that intermediate products can be exchanged between the two lines if one of the kilns or furnaces should require repair or maintenance (Nacken, 2000).

Billiton launched the expansion project in February 1999 when the nickel market began to recover from 2 years of depressed prices. In December 1999, the company closed on a $240 million loan, completing financing of the project. ABN AMRO Bank N.V., Barclays Capital (a division of Barclays plc), and four other banks participated in arranging the loan syndication. The syndicated loan, technically termed a debt facility, will mature in mid-2005 (Billiton plc, 1999).

In 2000, CMSA produced 27,720 t of Ni in ferronickel and exported 26,192 t, building up stocks in the process. Only 2,016 t, or 8% of CMSA's total exports, went to the United States. About 70% of the ferronickel exports went to Europe (International Nickel Study Group, 2001b, p. 30).

Cuba.—Metals Enterprise, the joint venture of the Cuban Government and Sherritt, produced 29,520 t of nickel-plus-cobalt in mixed sulfides at Moa in 2000—a record high output. The material provided about 90% of the feed for the venture's Fort Saskatchewan refinery in Alberta (Sherritt International Corp., 2001, p. 7). Mixed sulfide production at Moa has increased 126% since 1994, the year when the joint venture was formed.

European Union.—Finland.—On April 5, 2000, OMG bought the Harjavalta nickel plant in Finland from Outokumpu Oyj. OMG paid Outokumpu EUR 180 million in cash, which was equivalent at the time to about $172 million (Outokumpu Oyj, 2000a, b). (On April 6, 1 EUR was quoted at US$0.9583). OMG wanted to integrate the nickel plant with its Kokkola cobalt and nickel chemicals plant. The Kokkola plant was spun off from Outokumpu in 1991 when Mooney Chemicals, Inc. and Outokumpu merged their chemical businesses to form OMG. The nickel smelter at Harjavalta was not part of the April 5 transaction. Outokumpu continued to operate the smelter, processing nickel-copper concentrates from Outokumpu's mines in Australia. Outokumpu was also toll processing concentrates for OMG.

In 2000, the Harjavalta nickel plant produced about 50,600 t of refined nickel. The bulk of the nickel was recovered from matte produced at Outokumpu's smelter. The Outokumpu matte was supplemented with matte imported from Australia (8,982 t gross weight) and Brazil (15,835 t gross weight). The nickel was leached from the matte and separated from the other transition metals by solvent extraction. Most of the nickel was recovered as cathode by electrowinning. Some of the nickel, however, was reduced with hydrogen and made into briquets.

The 180 employees working at the Harjavalta plant were transferred to OMG. OMG has begun to more closely integrate the nickel plant with its Kokkola chemical operations. OMG will continue to supply nickel to Outokumpu's stainless steel melt shop at Tornio. Outokumpu will remain a copper and zinc producer but is planning to eventually give up nickel production when ore reserves at its mines in Finland and Australia are depleted.

European Union.—Netherlands.—ELG Haniel GmbH handled about 1.2 Mt of stainless steel scrap and related materials in 1999. Approximately 790,000 t were processed in Europe, mostly in Germany. The company recently moved the scrap processing facilities of Jewometaal Stainless Processing B.V., its Dutch subsidiary, to a new location in the Port of Rotterdam. The relocation and upgrading cost EUR 8 million and will allow Jewometaal to recycle and transship 220,000 t/yr of stainless steel scrap (ELG Haniel GmbH, 2000, p. 32-33).

Indonesia.—PT International Nickel Indonesia Tbk. (PT Inco) and AnTam continued to add mining and smelting capacity to their operations on the island of Sulawesi. Total mine production in 2000 for all of Indonesia was 98,200 t of contained nickel. All of the ore came from laterite deposits. Several joint ventures have been formed to explore and/or develop promising properties in Maluku.

Sulawesi.—PT Inco completed its 4-year expansion project, increasing the production capacity of its Soroako smelter by 50% to 68,000 t/yr of Ni in matte. The company added a fourth electric furnace smelting line and upgraded the existing three lines. At the end of 2000, PT Inco had 101 Mt of proven and probable reserves in the Soroako area averaging 1.82% Ni. The company has an additional 130 Mt of indicated resources averaging 1.80% Ni and 171 Mt of inferred resources averaging 1.82% Ni (Inco Ltd., 2001, p. 26).

In July 1999, AnTam announced that it would begin building a third line at its ferronickel smelter at Pomalaa. The third line would raise the capacity of the smelter from 11,000 t/yr of Ni in ferronickel to 24,000 t/yr. Money for the expansion was to come from funds raised in the company's initial public offering of November 1997. If all goes well, the third line could be operational by 2002 (PT Aneka Tambang (Persero) Tbk., 1999).

Gag Island.—On July 12, Falconbridge Ltd. and BHP Ltd. of Melbourne, Australia, announced that they had tentatively formed a joint venture to further evaluate nickel laterite deposits on Gag Island. Several matters, however, had to be resolved before the joint venture could become effective (Falconbridge Ltd., 2000). Commercial arrangements with AnTam, BHP's Indonesian partner, needed to be clarified. There were also some outstanding issues involving management of the island's forests. When these matters are resolved, Falconbridge will be able to acquire a 37.5% interest in the nickel project by contributing $75 million for a feasibility study. Falconbridge would be responsible for managing the 2-year study. BHP's current 75% interest would be reduced to 37.5% upon completion of the feasibility study. AnTam would retain its current 25% interest in the project.

Gag Island is about 40 km southeast of Gebe Island, Maluku,

Digitized by Google

where AnTam has one of its two principal nickel mines. BHP and AnTam have been working together on the Gag Island project since August 1996. BHP mining experts estimate that the Gag Island concession has 240 Mt of combined oxide and silicate resources averaging 1.35% Ni and 0.08% Co (BHP Ltd., 2000).

Halmahera Island.—Weda Bay Minerals Inc. of Vancouver, British Columbia, and AnTam have been jointly evaluating laterite deposits on Halmahera Island since May 1996. At least 11 areas between Cape Ulie and the Jira River were under investigation. The project is held under a contract of work between the Government of Indonesia and PT Weda Bay Nickel. PT Weda Bay Nickel is a joint venture of Weda Bay Minerals (90%) and AnTam (10%).

In February 2000, OMG agreed to work with Weda Bay Minerals and AnTam on the Halmahera project (OM Group Inc., 2000). OMG was to provide $18 million for a feasibility study in exchange for a 19.9% interest in Weda Bay Minerals. The feasibility study was scheduled to be completed in early 2002. If the feasibility study is positive, some of the Halmahera deposits could be in production as early as 2004. The nickel and cobalt would be recovered by pressure acid leaching. According to Weda Bay officials, the Halmahera deposits can supply the proposed PAL plant with 4 Mt/yr of ore for 30 years (Weda Bay Minerals Inc., 2000a, b). The PAL plant would produce some 30,000 t/yr of nickel and 3,000 t/yr of cobalt in value-added intermediate products (Metal Bulletin, 2000).

On August 16, Weda Bay Minerals announced that it had revised upward its estimates of nickel resources on the Halmahera concession by 73%. The total aggregate resource was now estimated to be 202 million dry tons of laterite averaging 1.37% Ni and 0.12% Co. The estimate included both indicated and inferred resources. The Santa Monica and Pinto deposits reportedly have an indicated resource, at a 1% nickel cutoff grade, of 60 million dry tons averaging 1.51 % Ni and 0.09% Co (Weda Bay Minerals Inc., 2000b).

New Caledonia.—Société Métallurgique le Nickel (SLN) accounted for 47% of New Caledonian mine production in 2000. The other 53% of mine production was divided among J.C. Berton Mines, Nickel Mining Corp., Société des Mines de la Tontouta (SMT), Société Minière du Sud Pacifique S.A. (SMSP), and several other independent mining companies. Mine production totaled 127,493 t on a contained nickel basis, up 16% from 110,062 t (revised) in 1999. In 2000, the French overseas territory exported 59,240 t of nickel in ore, which included 40,174 t of nickel in garnierite shipped to Japan and 19,066 t in limonitic laterites shipped to Australia. The remaining 68,300 t of nickel in ore was processed at the SLN smelter outside Doniambo (International Nickel Study Group, 2001b, p. 46-47).

SLN's Mining and Smelting Operations.—SLN operated the following four nickel mines: Thio, Kouaoua, Népoui-Kopéto, and Tiébaghi. (See figure 2.) A fifth mine, Kaala-Gomen (also known as Etoile du Nord), was operated by an SLN contractor. SLN's ore production was 5% greater than that of 1999. SLN and its subcontractors mined 3.71 Mt of wet lateritic ore, up from 3.52 Mt (revised). Garnierite ore accounted for 3.43 Mt or 92% of total production. The remaining 278,000 t was limonitic laterite. Eramet's management was evaluating a proposal to expand the new Tiébaghi Mine. In October, preparatory work was begun to resume mining laterites at Bonini in the Poro region. The Bonini mine site was abandoned in the early 1980s (Eramet Group, 2001, p. 30-35).

In 2000, the Doniambo smelter produced 43,914 t of nickel in ferronickel and 13,549 t of nickel in matte. The combined output of 57,463 t was an alltime high for Doniambo, edging out the previous record of 56,642 t set in 1999. A labor strike in February and March kept SLN from reaching its original production goal of 61,000 t. The refining capacity of the plant was 49,000 t/yr, while matte capacity was about 14,000 t/yr of contained nickel. SLN was planning to increase the annual capacity of Doniambo to 75,000 t sometime in 2004 or 2005 (Eramet Group, 2001, p. 30-35). Expansion of the smelter and improvement of operations at Tiébaghi were expected to cost a total of $180 million (Reuters Ltd., 2001).

The Paris-based Eramet Group controlled 60% of the shares of SLN, down from 90% in 1998. Eramet also had a 38.45% interest in Special Metals Corp.

Inco's Goro Project.—On December 13, Inco announced that it was hoping to complete its feasibility study of the Goro nickel-cobalt project by April 2001. The Goro deposits are at the southeastern tip of La Grande Terre, the main island. The mining and extraction project had advanced through several stages of planning and review since its inception in mid-1992. The Toronto-based nickel producer already had invested $50 million in an on-site pilot plant. The pilot-plant was being used to validate an advanced PAL process developed in-house to extract nickel and cobalt from lateritic ores. The plant was commissioned on October 22, 1999, and can process 12 metric tons per day of ore (Inco Ltd., 2000a, p. 24). Pilot-plant work to date indicates that the Inco process can be used successfully on a commercial scale. If financing can be arranged immediately after completion of the feasibility study, a full-size commercial facility could be operational by late 2004 or early 2005. The proposed mining and processing complex would have a production capacity of 54,000 t/yr of Ni in nickel oxide and 5,400 t/yr of Co in cobalt carbonate. A joint venture of Bechtel Overseas Corp. and Technip France S.A. would act as prime contractor during construction.

Inco was in the process of securing the necessary permits and clearances from the Government of New Caledonia to construct and operate the commercial facility. Inco and the Government have been discussing future taxes and financing arrangements for some time. The project's operating company, Goro Nickel S.A., is a wholly owned subsidiary of Compagnie Minière de Xere (CMX). CMX is a joint venture of Inco (85% equity) and Bureau de Recherches Géologiques et Minières—an agency of the French Government (15% equity).

Inco would continue to operate the Goro pilot plant after construction began and use the plant to train its future New Caledonian work force. The company has allocated $5 million for training and will build a training center near the pilot plant as part of the program. According to company officials, the Goro concession has more than 200 million dry tons of laterite ore, averaging 1.6% Ni and 0.17% Co. The initial mining zone has 47 Mt of proven and probable reserves (Inco Ltd., 2000e).

Inco was reportedly seeking a partner to help finance the $1.4 billion project and offset the investment risks (Platts Metals Week, 2001). Eramet has acknowledged that it has been contacted by Inco and has been evaluating the Canadian proposal. The Government of France, a stockholder in Eramet, has already committed $350 million for the Goro project.

Nakéty PAL Project.—Argosy Minerals Inc. and SMT were considering building a PAL plant at Nakéty on the east-central coast of La Grand Terre. SMT, an independent New Caledonian mining company, has been operating on the island for more than a decade. Argosy, an Australian-Canadian exploration and development company, was created on May 7, 1999, when Argosy Mining Corp. and Calliope Metals Corp. merged. The new company was headquartered in Vancouver, British Columbia.

In 1995, Calliope agreed to purchase ore from SMT, which holds several mining concessions at Nakéty. In 1998, Calliope Metals shelved plans to build a PAL facility in the Australian State of Queensland. The PAL facility was to have used New Caledonian ore supplied by SMT. A feasibility study by Kvaerner Metals ASA, however, indicated that the cost of exporting wet, unbeneficiated ore to Queensland—about $1.00 per pound Ni—would make the project uneconomical. The study concluded that it would be more cost effective to build the same facility adjacent to SMT's concessions at Nakéty. Over the long term, the savings in ore shipping charges would outweigh any additional costs incurred in building and operating the PAL plant on La Grand Terre (Russell, 2001). In May 1998, Argosy Mining Corp. and SMT tentatively agreed to form a joint venture to explore the feasibility of a PAL plant at Nakéty (Argosy Minerals Inc., 2000b). Ore for the plant would come from four of SMT's concessions: Barbouille, Belle Asashi 2, Lucienne 2, and Lucienne 2H. Argosy has continued to honor the agreements of its two predecessors. In August 1999, Argosy formed a joint venture with SMT to evaluate the Nakéty concessions. More than 675 holes have been drilled within the Nakéty deposit to date.

Dynatec Engineering Corp. has performed extensive metallurgical tests on the Nakéty ores, and Kvaerner has completed a preliminary engineering study of the deposit. According to Resources Service Group (an Argosy contractor), the Nakéty deposit has measured, indicated, and inferred resources in excess of 48 million dry tons that are estimated to average 1.42% Ni and 0.12% Co. Measured and indicated resources consist of 21.0 million dry tons of limonitic ore averaging 1.33% Ni and 0.14% Co and an additional 13.5 million dry tons of underlying, magnesium-rich saprolitic ore averaging 1.83% Ni and 0.06% Co. SMT is currently mining the saprolite zone on a small scale for export. The limonitic ore is reportedly better suited than the saprolite for pressure acid leaching (Argosy Minerals Inc., 2001b).

On July 24, 2000, Argosy and SMT agreed to include SMT's concessions at Bogota in the joint-venture agreement. The Bogota concessions are in the Canala area, about 3 km northwest of the proposed plant site near Nakéty. The 40 Bogota concessions cover 53.9 km^2, compared with only 10.4 km^2 for Nakéty. Reconnaissance drilling carried out by SMT in 1995 suggests that laterite mineralization underlies much of the iron-rich cap rock that trends northwest along the entire 18-km length of the Bogota Peninsula. Exploration efforts to date have focused on an 11-km^2 target area in the southern part of the peninsula (Argosy Minerals Inc., 2000b). The additional resources may allow Argosy to increase the design capacity of the proposed refinery. A total of 196 holes were drilled on 8 of the 40 Bogota concessions between 1982 and 1995. In some places, the thickness of the limonitic zone exceeded 35 meters (m). The number of drill holes to date is insufficient to make a rigorous resource estimate for the Bogota area (Argosy Minerals Inc., 2001b).

Argosy, like Inco, was actively seeking a partner for its project. On July 25, 2001, Argosy announced that the Norilsk Nickel Mining and Metallurgical Co. of Russia had agreed to participate in the evaluation (Argosy Minerals Inc., 2001a). Norilsk Nickel would provide the $20 million needed for a new bankable feasibility study of the Nakéty-Bogota laterites and would reimburse Argosy for part of the development company's expenditures to date. In exchange, Norilsk Nickel would earn a 50% to 70% interest in the joint venture.

Koniambo Project.—In 1998, Falconbridge, SMSP, and Société de Financement et d'Investissement de la Province Nord formed a joint venture to develop a nickel mining and smelting complex in the North Province. The smelter would have a capacity of 54,000 t/yr of nickel in ferronickel and use lateritic ores from the Koniambo massif as feedstock. Falconbridge would be allowed to earn up to a 49% interest in the project. The diamond drilling program on the Koniambo massif was completed during 2000. A total of 70,600 m of rock were drilled between August 1998 and December 2000. Based on this latest drilling, geologists now estimate that the massif has 151 Mt of inferred resources averaging 2.58% Ni and 0.07% Co (Falconbridge Ltd., 2001, p. 27-28).

Philippines.—Three companies mined laterite ore in 2000—Hinatuan Mining Corp., Rio Tuba Nickel Mining Corp., and Taganito Mining Corp. Combined production amounted to 20,208 t of contained nickel, 63% more than in 1999. None of the ore was smelted in the Philippines. About 50% of the material was exported to Japan; another 25% went to Australia. The remaining 25% was stockpiled in anticipation of the construction of a proposed PAL operation (International Nickel Study Group, 2001a; b, p. 48).

Mindoro Island.—Crew Development Corp. of Vancouver, Canada, has been evaluating a large nickel laterite deposit on the island of Mindoro. Mindoro is separated from Luzon on the north by the Verde Island Passage and is about 120 km south of Manila. According to company officials, the laterite deposit has at least 72 million dry tons of resources grading 0.94% Ni and 0.06% Co (Crew Development Corp., 2000a, b). Crew acquired the 110-km^2 concession when it merged with Mindex ASA, a Norwegian exploration company, in 1999. The proposed $700 million mining and hydrometallurgical extraction complex could produce as much as 40,000 t/yr of nickel and 3,050 t/yr of cobalt over its 30 years of operation.

The nickel and cobalt would be recovered using PAL technology similar to that employed in Western Australia. Natural gas for the project would come from a pipeline proposed by Philippine National Oil Co. and Royal Dutch/Shell Group. The pipeline would transport gas to Batangas from a new offshore field being developed near Palawan Island. The pipeline would pass within 6 km of Crew's proposed plant site. The sulfur needed for leaching the nickel would come from the Pamplona sulfur deposit on the island of Negros, 300 km to the southeast. Crew already holds all of the rights to the Pamplona concession (Northern Miner, 2000a, b). Cash costs for the Mindoro operation potentially could be reduced by selling 126,000 t/yr of byproduct ammonium sulfate. The Philippine rice and sugar cane industries currently consume about 400,000 t/yr of imported ammonium sulfate.

Palawan Island.—On April 20, Sumitomo Metal Mining Co. Ltd. of Japan and Rio Tuba announced that they were launching a joint study to determine if high pressure acid leach technology

Digitized by Google

could economically recover nickel at Rio Tuba's mine on Palawan Island (Reuters Ltd., 2000). The 500,000-t/yr open pit operation currently exports the bulk of its ore to Japan. The Rio Tuba ore typically grades 2.4% Ni. Philippine interests own 60% of Rio Tuba, while Japanese interests led by Pacific Metals Co. Ltd. (PAMCO) control the remaining 40%.

Sumitomo was hoping to complete the feasibility study by yearend 2000 and will be assisted by PAMCO. Sumitomo, the largest nickel producer in Japan, produces cathode and nickel salts at its Niihama refinery in Ehime Prefecture. PAMCO operates a ferronickel smelter at Hachinohe in Aomori Prefecture.

Russia.—The Russian Federation produced more more than 221,000 t of nickel in refined products (International Nickel Study Group, 2001b, p. 49-50). Norilsk Nickel was by far the largest producer in Russia, accounting for at least 218,000 t of nickel in metal or limited amounts of ferronickel, as well as 391,000 t of copper metal, and 4,650 t of cobalt. Norilsk Nickel produced 23% more nickel in 2000 than in 1996, when the company had a reported output of 177,185 t (Platt's Metals Week, 1998; Interfax International Ltd., 1999; RAO Norilsk Nickel, 1999a). A 1997 amendment to the Federation's Law on State Secrets prohibits Norilsk Nickel from divulging detailed production figures for its different subsidiaries.

RAO Norilsk Nickel.—In 2000, RAO Norilsk Nickel was the largest producer of nickel in the world, accounting for about 19% of total refinery production (RAO Norilsk Nickel, 2000a, b). The company was restructured in 2000 but continued to subsidize housing, the importation of food, and municipal services in the cities of Norilsk, Monchegorsk, and Zapolyarny. On January 4, 2000, officials of the LME agreed to accept two major nickel products made by Norilsk—full-size nickel cathode sheet (H-1) and full-size sheet with uncut edges (H-1Y).

In 1998, RAO Norilsk Nickel launched a 10-year development program aimed at modernizing operations on both the Kola Peninsula and the Taimyr Peninsula. The program required raising $3 billion to $5 billion from foreign investors. Norilsk Mining Co. was created to manage the A.P. Zavenyagin Norilsk Mining and Metallurgical Combine on the Taimyr Peninsula. The Kola Metallurgical and Mining Co, a second new entity, was to oversee the Pechenganickel Mining and Metallurgical Combine, the Severonickel Combine, and related activities on the Kola Peninsula (RAO Norilsk Nickel, 1999b).

The International Finance Company Bank, Norilsk's financial consultant, was to be responsible for developing the necessary market instruments needed to attract the initial $200 million. INTERROS Holding Co. of Russia would guarantee the investments under a "repo" agreement that could give INTERROS a 37.9% stake in Norilsk Mining Co. (Budrys, 2000). An additional $800 million would have to be raised before January 2003 if the program was to keep on schedule. The initial $200 million would be used to expand Norilsk Nickel's product line, improve sales to Russian consumers, create an overseas sales network, and improve the company's transport infrastructure.

The 10-year development program would allow Norilsk Mining Co. and Kola Metallurgical and Mining Co. to develop new levels in existing underground mines, construct new mines, and carry out local exploration work designed to transform inferred resources into measured reserves. If the plans are fully implemented, the Kola Combine would remain open past 2007 and possibly continue to operate until 2015 (RAO Norilsk Nickel, 2000b).

Expansion of Operations on the Taimyr Peninsula.—Mine development work to replace declining reserves has intensified, even though some 50 years of reserves still exist. The bulk of the Taimyr ores comes from the Oktyabr and the Talnakh deposits. The two deposits reportedly contain more than 35% of the world's nickel reserves (RAO Norilsk Nickel, 2000a). Production from the new Skalisty Mine will help offset declining output at some of the older mines. Increased production of disseminated "impregnation" ores and high-grade copper ores should compensate for declining production of high-nickel, massive sulfide ores.

The first stage in the development of the Pelyatka gas condensate field was completed in 2000. Construction of a pipeline from the field to Norilsk was well underway and was critical to the Taimyr expansion program. By yearend, 123 km of pipelines had been installed. The first gas was scheduled to reach Norilsk sometime in 2001. The initial gas flow was to be about 1.4 million cubic meters per day (RAO Norilsk Nickel, 2001, p. 10).

Questions About the Legitimacy of Norilsk's Privatization.—On June 20, 2000, a Moscow city prosecutor filed a lawsuit seeking to overturn the privatization of Norilsk Nickel (Mining Journal, 2000b). The lawsuit could complicate future company plans to raise capital for modernization and development. The lawsuit questioned the legality of the 1995 loans-for-shares program that preceded privatization of the giant parastatal enterprise. Under the program, the Russian Government used its equity in Norilsk Nickel as collateral to obtain a $170 million loan from United Export-Import Bank Open Joint Stock Co. (UNEXIM Bank). The original agreement gave UNEXIM Bank, now part of INTERROS, control of 51% of Norilsk Nickel's voting stock. The Russian Government never repaid the loan and Norilsk Nickel was subsequently sold at auction to ZAO SVIFT, an affiliate of UNEXIM Bank, for about $250 million.

UNEXIM Bank is rescheduling its foreign debt, undergoing restructuring, and may merge with ROSBANK, another INTERROS financial institution. On May 22, holders of UNEXIM Bank eurobonds ratified key parts of the restructuring plan. Fleming UCB is serving as financial adviser to UNEXIM Bank (INTERROS Holding Co., 2000).

Enterprises in the Ural Mountains.—The board of directors of RAO Yuzhural Nickel were considering turning over key assets—a nickel smelter and a hydrometallurgical plant used to produce cobalt—to Uraltransgaz, the company's gas supplier, in exchange for a forgiveness of debts. Uraltransgaz is already the largest shareholder in Yuzhural Nickel. The Orenburg Copper-Nickel Co., which has a 20% interest in the nickel producer, opposed the asset-debt swap. The Orenburg Copper Nickel Co. is a parastatal controlled by the Orenburg Regional Administration (Interfax International Ltd., 2000).

Venezuela.—The new Loma de Niquel mining and smelting complex was in the final stages of construction begun in October 1997. The site (formerly Loma de Hierro) is about 80 km southwest of Caracas. For more than 50 years, a string of companies had been evaluating the laterite deposit. The complex was designed to produce 17,500 t of Ni in ferronickel and began smelting ore in December 2000. Full capacity should be reached by 2001 (Minera Loma de Niquel, C.A., 2000).

Yemen.—Canadian Mountain Minerals (Yemen) Ltd. (CMMY), a wholly owned subsidiary of Cantex Mine Development Corp., has been exploring a 40,000-km^2 area on the western margin of the Rubh al-Khali (*English* Great Sandy Desert) since January 1996 (Cantex Mine Development Corp., 1999a). In late 1999, CMMY drilled two holes into a portion of the Suwar ultramafic complex where the overlying soils were anomalously high in copper and nickel (Cantex Mine Development Corp., 1999b). On February 22, 2000, Cantex announced that both drill holes had intersected massive nickel and copper sulfide mineralization (Cantex Mine Development Corp., 2000a). The complex is located in the Maswar district of Hajjah Governorate, about 60 km west of Sana'a, the capital of Yemen. The principal rock types in the ultramafic complex are gabbro-norite, peridotite, and olivine gabbro.

The bulk of the sulfide mineralization in the two discovery holes was at depths of 40 to 70 m. The first hole intercepted 18.7 m of mineralization averaging 0.89% Ni, 0.67% Cu, and 0.046% Co. The second hole intercepted 22.1 m of mineralization averaging 1.41% Ni, 0.91% Cu, and 0.07% Co (Cantex Mine Development Corp., 2000a). The sulfide-rich sections also contained anomalous amounts of silver and PGM (Cantex Mine Development Corp., 2000d).

In the first half of 2000, CMMY drilled eight additional holes near the two discovery holes in an area now referred to as the Suwar north zone. Seven of the eight holes also intersected significant sulfide mineralization, with peak nickel values ranging from 0.43% to 1.64%. Mineralization was subsequently found in a second area, 1.6 km southwest of the two discovery holes. This second area is now referred to as the Suwar south zone. Three holes were drilled in the south zone where anomalous values of palladium and platinum as well as copper, nickel, and cobalt were present in soil and rock chips. One drill hole intersected a 6.7-m-thick sulfide section assaying 1.23% Ni, 0.45% Cu, 0.113% Co, and 2.02 g/t of silver (Cantex Mine Development Corp., 2000c).

On July 4, CMMY and Falconbridge International (Investments) Ltd. formed a joint venture to evaluate the Suwar discovery. Falconbridge International (Investments) is a wholly owned subsidiary of Falconbridge Ltd., one of the five largest nickel producers in the world. Under the joint-venture agreement, Falconbridge can earn up to a 60% working interest in the Suwar mining lease. The two Canadian partners are hoping to construct a mine and mill within 4 years if a proposed feasibility study is positive (Cantex Mine Development Corp., 2000b). In November, Falconbridge International was finishing up a ground electromagnetic survey of the Suwar complex but decided to suspend surveying until after the Ramadan holiday. The geophysical data were to be used to generate targets for the 2001 drilling program.

The Prime Minister of Yemen reportedly has commissioned the surveying and planning of a 42-km-long access road to the Suwar property. The access road would tie into an existing highway at a point 145 km from the Red Sea port of Hodeidah.

Current Research and Technology

Researchers Synthesize Organo-Nickel Compound that Behaves Like a Metal.—Japanese researchers have synthesized an organo-nickel compound that behaves like a metal. The new crystalline material reportedly is the first synthetic metal built from a single, neutral molecular component (Chemical and Engineering News, 2001). Previously synthesized molecular metals have had two or more components. The compound is referred to as $Ni(tmdt)_2$, where tmdt is trimethylene-tetrathiafulvalene-dithiolate. Resistivity and magnetic susceptibility measurements indicate that $Ni(tmdt)_2$ is metallic over a temperature range from 0.6 K (Kelvin) to room temperature, 296 K. Single crystal diffraction analysis revealed that $Ni(tmdt)_2$ has a triclinic crystal structure (Tanaka and others, 2001).

A conventional metal typically has good electrical and thermal conductivities, ductility, and reflectivity and usually exhibits high strength. These properties are related to a structure in which the positively charged ions are bonded through a field of free electrons (i.e., electron gas) which surrounds them. The $Ni(tmdt)_2$ molecule has 12 sulfur atoms bonded to carbon, forming a string of five-membered, heterocyclic rings. Because of this complex resonating ring structure, the new compound exhibits some of the characteristics of graphite and benzene.

The Japanese research team was composed of scientists from the Institute for Molecular Science in Okazaki and the Research Centre for Spectrochemistry at the University of Tokyo. The team focused on $Ni(tmdt)_2$ after finding in 1999 that an analogous nickel molecule, propylene-dithiotetrathiafulvalene-dithiolate [$Ni(ptdt)_2$], behaved like a semiconductor. The latest discovery may open new avenues for the preparation of molecule-based metals and novel superconductors.

Commercialization of Fuel Cells.—On September 21, Texaco Energy Systems, Inc. and ECD formed a 50-50 joint venture to commercialize regenerative fuel cells. ECD will provide proprietary technology and fuel cell development expertise. ECD has been developing an advanced automotive fuel cell that utilizes low-cost, nonnoble metal catalytic materials (Texaco Energy Systems, Inc. and Energy Conversion Devices, Inc., 2000).

In a fuel cell-powered automobile, hydrogen gas is used in place of gasoline. The fuel cell generates electric power for the automobile motor by combining the hydrogen with oxygen to form water vapor. The oxygen is in air drawn into the cell from the outside atmosphere. ECD has proposed storing the hydrogen in a metal hydride system the size of a conventional gasoline tank. The metal hydride matrix minimizes the possibility of a hydrogen explosion. For additional information, see Dunn (1999), Goes (1999), and Mangan (1999).

Outlook

There is little chance that ferronickel production in the United States can be revived in the near term. The use of PAL technology to recover nickel from lateritic ores in New Caledonia, the Philippines, and Western Australia is expected to keep nickel prices in check for at least a decade. The combined rate of refined nickel production for the three existing Australian PAL operations passed the 9,000 t/yr mark at the beginning of 2001 and was expected to keep growing for at least another 3 years, eventually surpassing 100,000 t/yr. Plans to develop additional lateritic nickel deposits in the Kalgoorlie region of Western Australia have accelerated since the Goldfields natural gas pipeline was completed in late 1996 (Griffiths, 2000). The availability of inexpensive natural gas from offshore fields on the North West Shelf of the Indian Ocean has made it economically possible to produce refined

Digitized by Google

nickel at several other laterite deposits previously rejected because of their remote locations. At least part of the new ferronickel production from Cerro Matoso (Colombia) and Loma de Níquel (Venezuela) has begun to come to the United States. The proposed Goro and Koniambo projects in New Caledonia would put additional material into the U.S. supply line.

The immense resources of the Voisey's Bay nickel-copper-cobalt deposit in northeastern Labrador (Canada) continue to overshadow the market. Inco and the Provincial Government of Newfoundland could reach an agreement at any time on developing the sub-Arctic deposit. Depending on market conditions, the proposed Voisey's Bay mining and milling complex would be capable of producing from 60,000 to 123,000 t/yr of nickel in sulfide concentrates. In Ontario, Falconbridge and Inco continue to find new ore along the edges of the Sudbury Basin. In Manitoba and Quebec, exploration crews have identified several promising occurrences for future followup.

The long-term outlook for increased nickel consumption is extremely positive, despite the recent economic crises in East Asia. Several forces are helping to sustain long-term growth in nickel consumption. The population of the world continues to grow. Faster transport, the explosive expansion of telecommunications systems, and the globalization of markets are making society as a whole increasingly dependent on products fabricated from sophisticated starting materials, many of which contain significant quantities of nickel. A technologically advancing society is continually demanding new materials with improved resistance to corrosion and heat, again favoring nickel.

Demand for austenitic stainless steel will continue to drive the world nickel market for at least another 20 years. For the present, growing demand for stainless steel in China, Europe, and the Western Hemisphere has offset weak demand in Japan. Beginning in 2002, world stainless steel consumption is forecast to grow between 2% and 5% per year to the year 2007. After 2007, the growth rate could rise even more, perhaps reaching 9% at some point, if the Russian economy turns around. The outlook for stainless steel production in the United States remains positive despite the growth in steel imports. Stainless steel production in the United States could exceed 2.6 Mt in 2002—an all time high for the country. The austenitic share of the production is expected to remain unchanged at 59%. This percentage is lower than corresponding austenitic percentages reported by other member countries of the Organization for Economic Cooperation and Development because the U.S. automobile manufacturing industry consumes more than 500,000 t/yr of ferritic stainless, about 18% of total U.S. stainless consumption.

Demand for nickel-bearing superalloys is expected to grow. The aerospace industry has been gradually shifting from a defense-oriented market to one that is more evenly balanced between commercial and Government purchases. Advanced nickel and titanium alloys are increasingly being incorporated in aircraft.

Batteries now constitute a bigger market for nickel in the United States than either coinage or traditional copper-nickel alloys. The use of nickel in batteries is growing at a much faster rate than the use of nickel in steel, although the tonnages going into batteries are still small. The market for nickel-based batteries is expected to grow at least 6% per year during the next 10 years even if American and Japanese automobile manufacturers decide to substitute lithium-ion cells for nickel-metal hydride cells in their third-generation EVs or second-generation hybrid vehicles. Automobile manufacturers are considering replacing the current 12-volt electrical systems in vehicles with 42-volt systems. If adopted, the change could drastically change the types of metals used in batteries for conventional automobiles. A NiMH battery has a higher energy density and longer cycle life than its advanced lead-acid counterpart. Performance and environmental requirements favor the NiMH battery, but problems starting the automobile at low temperatures need to be resolved (Jouhanneaud, 2001).

TABLE 1
SALIENT NICKEL STATISTICS 1/

(Metric tons of contained nickel, unless otherwise specified)

	1996	1997	1998	1999	2000
United States:					
Mine production	1,330	--	--	--	--
Plant production	15,100	16,000	4,290	--	--
Secondary recovery from purchased scrap:					
From ferrous scrap	48,800	58,200	52,700	58,600	71,700
From nonferrous scrap	10,500	10,200	10,400	12,400 r/	12,200
Shipments of purchased scrap 2/	84,900	97,600	89,700 r/	93,000 r/	123,000
Exports:					
Primary	13,100	16,400	8,440	7,440 r/	8,150
Secondary	33,600	40,200	35,100	31,400	49,900
Imports for consumption:					
Ore	15,000	17,600	1,420	--	--
Primary	142,000	147,000	148,000	139,000	156,000
Secondary	8,060	11,000	8,500	9,480	10,700
Consumption:					
Reported:					
Primary	118,000 r/	120,000 r/	116,000 r/	116,000 r/	115,000
Secondary (purchased scrap) 3/	59,300	68,400	63,100 r/	71,000	84,000
Total	177,000 r/	188,000 r/	179,000 r/	187,000 r/	199,000
Apparent:					
Primary	146,000	154,000 r/	149,000 r/	140,000 r/	147,000
Secondary (purchased scrap) 4/	33,700	37,700	36,900 r/	49,400 r/	42,000
Total	180,000	192,000 r/	186,000 r/	190,000 r/	189,000
Apparent primary plus reported secondary	206,000	222,000 r/	212,000 r/	211,000 r/	231,000
Stocks, yearend:					
Government	15,900	8,530	2,600	--	--
Producers and traders	13,300	12,600	13,100	12,700	12,300
Consumer, primary	9,270	10,400 r/	10,500 r/	4,850 r/	6,490
Consumer, secondary	4,230	5,770	5,460 r/	5,070	7,860
Total	42,700	37,300	31,700 r/	22,600 r/	26,600
Employment, yearend:					
Mine	8	7	7	1	1
Smelter	253	264	6	6	(5/)
Port facility	23	22	1	1	--
Price, cash, London Metal Exchange:					
Per metric ton, average annual	$7,501	$6,927	$4,630	$6,011	$8,638
Per pound, average annual	$3	$3	$2	$3	$4
World, mine production	1,060,000	1,120,000 r/	1,130,000 r/	1,120,000	1,250,000

r/ Revised. -- Zero.

1/ Data are rounded to no more than three significant digits, except prices; may not add to totals shown.

2/ Defined as scrap receipts less shipments by consumers plus exports minus imports plus adjustments for consumer stock changes.

3/ More nearly represents amount consumed than does apparent secondary consumption.

4/ Internal evaluation indicates that apparent secondary consumption is considerably understated.

5/ The smelter at Riddle, OR, was decommissioned in 2000.

TABLE 2
NICKEL RECOVERED FROM PURCHASED SCRAP IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY

(Metric tons of contained nickel)

	1999	2000
Kind of scrap:		
Aluminum-base 2/	4,450	4,290
Copper-base	2,860	3,310
Ferrous-base 3/	58,600	71,700
Nickel-base	5,120 r/	4,620
Total	71,000	84,000
Form of recovery:		
Aluminum-base alloys	4,450	4,290
Copper-base alloys	5,160 r/	5,300
Ferrous alloys	58,600	71,800
Nickel-base alloys	2,780 r/	2,610
Miscellaneous and unspecified	2	1
Total	71,000	84,000

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Primarily borings and turnings of wrought alloys, such as 2218, 2618, 4032, and 8280, or special casting alloys, such as 203.0.
3/ Primarily stainless and alloy steel scrap consumed at steel mills and foundries.

TABLE 3
REPORTED U.S. CONSUMPTION OF NICKEL, BY FORM 1/

(Metric tons of contained nickel)

Form	1999	2000
Primary:		
Metal	95,600 r/	94,600
Ferronickel	12,800 r/	13,500
Oxide and oxide sinter 2/	5,160	3,610
Chemicals	1,660	1,340
Other	1,200 r/	1,590
Total	116,000 r/	115,000
Secondary (scrap) 3/	71,000	84,000
Grand total	187,000 r/	199,000

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes chemical-grade oxide.
3/ Based on gross weight of purchased scrap consumed and estimated average nickel content.

TABLE 4
U.S. CONSUMPTION OF NICKEL IN 2000, BY USE 1/

(Metric tons of contained nickel)

Use	Metal	Ferro-nickel	Oxide and oxide sinter	Chemicals	Other forms	Total primary	Secondary (scrap)	Grand total 2000	Grand total 1999
Cast irons	54	W	--	--	60	114	54	168	495 r/
Chemicals and chemical uses	347	W	W	644	--	991	--	991	1,580 r/
Electric, magnet, expansion alloys	479	--	--	--	--	479	W	479	525 r/
Electroplating (sales to platers)	15,600	--	--	39	W	15,700	--	15,700	15,400 r/
Nickel-copper and copper-nickel alloys	5,570	W	W	--	16	5,590	4,370	9,960	10,500
Other nickel and nickel alloys	15,500	67	W	--	89	15,700	2,510	18,200	15,200
Steel:									
Stainless and heat resistant	21,100	13,200	3,360	W	153	37,800	70,400	108,000	102,000 r/
Alloys (excludes stainless)	5,370	85	147	--	776	6,370	1,330	7,700	8,100 r/
Superalloys	18,900	--	W	W	441	19,400	W	19,400	18,900 r/
Other 2/	11,600	68	107	651	59	12,500	5,350	17,800	15,200 r/
Total	94,600	13,500	3,610	1,330	1,590	115,000	84,000	199,000	187,000 r/
Total all companies, apparent	XX	XX	XX	XX	XX	147,000	42,000	189,000	190,000

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Other." XX Not applicable. -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes batteries, catalysts, ceramics, coinage, other alloys containing nickel, and data indicated by symbol "W."

TABLE 5
NICKEL IN CONSUMER STOCKS IN THE UNITED STATES, BY FORM, DECEMBER 31 1/

(Metric tons of contained nickel)

Form	1999	2000
Primary:		
Metal	3,610 r/	4,720
Ferronickel	430 r/	768
Oxide and oxide sinter	390	610
Chemicals	224 r/	188
Other	194 r/	202
Total	4,850 r/	6,490
Secondary (scrap)	5,070	7,860
Grand total	9,920 r/	14,300

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.

TABLE 6
U.S. EXPORTS OF NICKEL PRODUCTS, BY CLASS 1/

Class	1999 Quantity (metric tons)	1999 Value (thousands)	2000 Quantity (metric tons)	2000 Value (thousands)
Unwrought primary (contained nickel):				
Cathodes, pellets, briquets, shot	831	$6,610	1,690	$15,100
Ferronickel	59	161	37	202
Powder and flakes	909	14,200	1,260	18,700
Metallurgical-grade oxide	1,470	2,730	1,930	6,350
Chemicals (contained nickel):				
Catalysts	3,360	110,000	1,880	70,100
Salts 3/	803	6,860	1,350	13,800
Total	7,440	140,000	8,150	124,000
Unwrought secondary (contained nickel):				
Stainless steel scrap	19,500	151,000	35,100	310,000
Waste and scrap	12,000	40,300	14,800	60,900
Total	31,400	192,000	49,900	371,000
Grand total	38,900	332,000	58,100	495,000
Wrought (contained nickel):				
Bars, rods, profiles, wire	382	4,300	520	9,200
Sheets, strip, foil	280	4,700	741	13,000
Tubes and pipes	260	2,550	147	1,550
Total	,922	11,500	1,410	23,700
Alloyed (gross weight):				
Unwrought alloyed ingot	9,140	76,100	9,850	91,400
Bars, rods, profiles, wire	6,360	101,000	7,270	120,000
Sheets, strip, foil	7,430	90,500	7,930	112,000
Tubes and pipes	828	20,400	1,010	23,900
Other alloyed articles	3,550	82,400	2,670	86,500
Total	27,300	371,000	28,700	433,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ The nickel contents are as follows: metallurgical-grade oxide, 77%; waste and scrap, 50%; and stainless steel scrap, 7.5%. The salts category contains the following: chemical-grade oxide, sesquioxide, and hydroxide, 65%; chlorides, 25%; and sulfates, 22%. Other salts and various catalysts are assumed to be 22% nickel.
3/ Excludes nickel carbonate (see Schedule B 2836.99.9050).

e/ Estimated. p/ Preliminary. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Insofar as possible, this table represents recoverable mine production of nickel. Where actual mine output is not available, data related to a more highly processed form have been used to provide an indication of the magnitude of mine output and this is noted parenthetically. North Korea may have an active nickel mine, but information is inadequate to make reliable estimates of output. Table includes data available through July 27, 2001.

3/ The Government of Cuba reports plant production on a contained nickel plus cobalt basis. The tonnages shown in this table for Cuba have been adjusted downward to correct for the cobalt. The cobalt content was determined to be 1.16% for granular and powdered oxide, 1.21% for oxide sinter, 7.56% for sulfide precipitate, and 25% for ammoniacal leach precipitate.

TABLE 11--Continued
NICKEL: WORLD PLANT PRODUCTION, BY COUNTRY AND PRODUCT 1/ 2/

e/ Estimated. p/ Preliminary. r/ Revised. -- Zero.
1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.
2/ Table includes data available through July 27, 2001.
3/ In addition to the countries listed, North Korea is believed to have produced metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels. Several countries produce nickel-containing matte, but output of nickel in such materials has been excluded from this table to avoid double counting. Countries producing matte for export are listed in table 12.
4/ Includes estimated production of pressure acid leach operations.
5/ Brazil produced nickel carbonate (an intermediate product), in metric tons: 1996--9,210; 1997--10,487; 1998--13,133; 1999--17,153; and 2000--17,223.
6/ Nickel contained in products of smelters and refineries in forms, which are ready for use by consumers. Figures include the nickel content of nickel oxide sinter exported to the Republic of Korea and Taiwan. See footnote 8.
7/ Cuba also produces nickel sulfide but, because it is used as feed material elsewhere, it is not included to avoid double counting. Combined output of processed sulfide and ammoniacal liquor precipitate was, as follows, in metric tons of contained nickel: 1996--24,490 (revised); 1997--25,310 (revised); 1998--26,561 (revised); 1999--26,118 (revised); and 2000--28,413. See table 12.
8/ Reported by Eramet for Sandouville. Excludes secondary production from spent rechargeable batteries.
9/ Nickel metal production for the Republic of Korea and Taiwan are not included because the production is derived wholly from imported metallurgical-grade oxides and to include them would result in double counting. Metal estimates are as follows, in metric tons: the Republic of Korea: 1996--18,000 (revised); 1997--18,452 (revised); 1998--20,183; 1999--20,235; and 2000--29,890; and Taiwan: 1996--10,000; 1997-1998--10,5000; and 1999-2000--10,000.
10/ Nickel content of nickel sulfate ($NiSO_4 \sim 6H_2O$). Most of the nickel sulfate was a byproduct of the concentrating, smelting, and refining of domestically mined copper ores. Some production, however, may have been derived from imported nickeliferous raw materials that were blended with the domestic copper concentrates.
11/ Includes production from sulfidized concentrates shipped from Cuba for toll refining.
12/ Include nickel sulfate plus exported metal in concentrate.
13/ Data represent production from domestic nickel ore.
14/ Previously published as "Other, metal." Data represent production from imported Botswanan matte and South African nickel sulfate.
15/ See "Zimbabwe, metal, toll refined from imported materials."

TABLE 12
NICKEL: WORLD PRODUCTION OF INTERMEDIATE PRODUCTS FOR EXPORT, BY COUNTRY 1/ 2/

(Metric tons of nickel content)

Country	1996	1997	1998	1999	2000
Matte:					
Australia 3/	28,768	37,010	47,459	28,190	41,771

NITROGEN

By Deborah A. Kramer

Domestic survey data and tables were prepared by Feri Naghdi, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Nitrogen (N) is an essential element of life and a part of all plant and animal proteins. As a part pf the DNA and RNA molecules, N is an essential constituent of each individual's genetic blueprint. As an essential element in the chlorophyll molecule, N is vital to a plant's ability to photosynthesize. Some crop plants, such as alfalfa, soybeans, garden peas, and peanuts, can convert atmospheric nitrogen into a usable form in a process called fixation. Most nitrogen available for crop production, however, comes from decomposing animal and plant waste or from commercially produced fertilizers.

All commercial fertilizers contain their nitrogen in the ammonium and/or nitrate form or in a form that is quickly converted to these forms once the fertilizer is applied to the soil. Commercial production of anhydrous ammonia is based on reacting nitrogen with hydrogen under high temperatures and pressures. The source of nitrogen is air, which is almost 80% nitrogen. Hydrogen is derived from a variety of raw materials, including water and crude oil, coal, or natural gas hydrocarbons. Other nitrogen fertilizers are produced from ammonia feedstocks through a variety of chemical processes. Small quantities of nitrates are produced from mineral resources principally in Bolivia and Chile.

In 2000, U.S. ammonia production was 12.3 million metric tons (Mt) of contained N, a 5% decline from that in 1999. Although the United States produced most of its ammonia requirements, imports, mainly from Canada, Russia, and Trinidad and Tobago, supplied a portion of consumption. Apparent consumption of ammonia also decreased by 5%. About 88% of the ammonia was used in fertilizer applications.

By yearend, the skyrocketing price of natural gas in the United States resulted in the temporary closure of significant quantities of ammonia production capacity. At the end of 2000, about 5.6 Mt of annual capacity was closed (including permanent facility closures). The closure of this ammonia capacity led to closures at urea and urea ammonium nitrate solution (UAN) plants because of the lack of ammonia feedstock. Several producers were selling their natural gas futures instead of producing ammonia. Two ammonia facilities—one in Louisiana and one in Oklahoma—were permanently closed during the year, and a new plant that uses petroleum coke as a feedstock opened in Kansas.

Global ammonia production in 2000 increased by about 2% from that of 1999 to about 109 Mt of contained N. China, India, and the United States continued to be the principal producers. In 2000, world urea production increased slightly to 49.4 Mt of contained N. Urea exports increased by nearly 9% to 12.0 Mt of contained N. China and India, the two largest producing countries, accounted for 47% of world production; production in China increased by about 2% and production in India decreased by 1% compared with those of 1999. The

Ammonia in the 20th Century

Prior to the 20th century, sources of fixed nitrogen compounds were limited to natural organic materials, natural nitrates, and coke-oven byproducts. By 1910, two techniques for nitrogen fixation were commercially established but required significant quantities of energy. During the first decade of the 20th century, the worldwide demand for nitrogen-based fertilizers exceeded the existing supply. The largest source of nitrogen was found in a huge guano deposit (essentially sea bird droppings) that was 350 kilometers in length and 1.5 meters thick and was located along the coast of Chile. This natural source of ammonia and nitrogenous compounds, however, was disappearing quickly. Fritz Haber invented a large-scale catalytic synthesis of ammonia from elemental hydrogen and nitrogen gas, reactants that are abundant and inexpensive. The original laboratory-scale process was first demonstrated in 1909 and patented by Haber in 1910. Carl Bosch and Friedrich Bergius contributed the invention and development of chemical high-pressure methods of ammonia production, which allowed higher ammonia yields. [These advances in ammonia production methods were the basis for two Nobel Prizes in chemistry—Haber in 1918 and Bergius and Bosch in 1931.] Although the original process has been modified since its development, mostly to improve processing efficiencies, the Haber-Bosch process remained the basis of ammonia production facilities through the end of the 20th century. With the advent of inexpensive ammonia production, consumption of ammonia increased rapidly. Statistical data for ammonia were not available before 1942, but U.S. consumption was estimated to be about 400,000 metric tons per year in the 1940s, with 80% of that used for agriculture. During World War II, demand for ammonia escalated because of the need for ammonium-base munitions. After the end of the war, ammonia demand continued to increase because additional fertilizer was required to grow food for a growing population.

By 2000, the United States, China, and India had become the three largest producers of ammonia in the world. Of a total world production of 109 million metric tons nitrogen content, these three countries produced nearly one-half; U.S. production was about 13 million tons of nitrogen content. The principal use for ammonia remained as a fertilizer, which accounted for about 88% of the total ammonia consumption in the United States. A significant quantity of ammonia was used to produce a variety of downstream products that included urea, ammonium nitrate, ammonium sulfate, and nitric acid, which also were used mainly as fertilizers.

Digitized by Google

United States and Canada produced about 11% of the total. China continued its ban on imports of urea and supplied its needs with domestic production. With the passage of the U.S.-China Relations Act of 2000 (Public Law 106-286) and the pending membership of China in the World Trade Organization (WTO), this ban may be lifted.

Legislation and Government Programs

In October, the U.S.-China Relations Act of 2000 was enacted into law. As part of its provisions, the law normalized trade relations with China, ending the annual congressional review of China's normal-trade-relations (NTR) status, and stated that the United States should ask the WTO to monitor China's performance annually as part of China's admission to the organization (CBS News, October 10, 2000, Clinton inks China trade bill, accessed May 23, 2001, at URL http://www.cbsnews.com/now/story/0,1597,234529-412,00.shtml). As a result of granting permanent NTR status to China, the fertilizer industry can benefit from a U.S.-China market access agreement that was signed in 1999. Under the agreement, a tariff rate quota for urea and diammonium phosphate (DAP) would be established, and the importation of a certain quantity of urea and DAP through China's private sector would be allowed. The agreement set tonnage quantities that would be subject to an in-quota tariff rate of 4%. Any imported tonnage above this number would be subject to a 50% tariff rate unless the Chinese Government chooses to waive applying the higher rate. For DAP, the in-quota tonnage would begin with 5.4 Mt and increase to 6.9 Mt by the sixth year. For urea, the in-quota tonnage would start at 1.3 Mt and increase to 3.3 Mt in the sixth year (Green Markets, 2000b).

On October 13, the Committee for Fair Ammonium Nitrate Trade filed a petition with the U.S. International Trade Commission (ITC) alleging that ammonium nitrate from Ukraine was being sold in the United States at less than fair value. As a result, the ITC began an antidumping investigation of imports of ammonium nitrate from Ukraine and determined that there was a reasonable indication that the domestic industry was being injured (U.S. International Trade Commission, 2000). The International Trade Administration (ITA), U.S. Department of Commerce, began its investigation into the antidumping allegation in November and made a preliminary determination in March 2001. According to the ITA's investigation, the estimated dumping margin for J.S.C. "Concern" Stirol was 113.38% ad valorem. The Ukraine-wide rate, which was applicable to all other producers and exporters, was also 113.38%. The ITA also determined that critical circumstances existed. A final determination was set to be completed 105 days after the notice was published in the Federal Register (U.S. Department of Commerce, 2001).

In July, the U.S. Environmental Protection Agency (EPA) established a final rule on how and when States must move to limit nutrient levels and pollution in water bodies. According to the EPA rule, States, territories, and authorized tribes would be required to develop more comprehensive lists of all water bodies that do not attain and maintain water-quality standards. They also would need to establish all necessary total maximum daily loads (TMDLs) over a 10-year period, with an allowance for another 5 years where necessary. The rule also specified elements of approvable TMDLs, including implementation plans containing lists of actions and expeditious schedules to reduce pollutant loadings. The rule established specific timeframes under which the EPA would ensure that lists of waters and TMDLs are completed as scheduled and necessary National Pollutant Discharge Elimination System (NPDES) permits are issued to implement TMDLs. The final rule explained the EPA's discretionary authority to object to and reissue, if necessary, State-issued NPDES permits that have been administratively continued after expiration where there is a need for a change in the conditions of the permit to be consistent with water-quality standards and established and approved TMDLs (U.S. Environmental Protection Agency, 2000).

In June, the Governors of Maryland, Virginia, and Pennsylvania, the Mayor of Washington, DC, and the Administrator of the EPA signed the new Chesapeake Bay Agreement, which established regional standards for Bay restoration over the next 10 years. Included in these standards is a cap on nitrogen and phosphorus loading, which would remain at the existing level of 40% (Governor's Office of the State of Maryland, June 28, 2000, Governor Glendening, leaders from neighboring States sign historic agreement to preserve Chesapeake Bay, accessed June 11, 2001, at URL http://www.gov.state.md.us/gov/press/2000/jun/html/chesbao.html).

Production

Industry statistics for anhydrous ammonia and derivative products were developed by the U.S. Census Bureau. A summary of the production of principal inorganic fertilizers by quarter was reported in the series MQ325B, and industrial gases (including nitrogen) were reported in the quarterly report MQ325C. Final data for inorganic fertilizers were subsequently published in the companion annual report MA325B, and data for industrial gases were published in the annual report MA325C.

In 2000, production of anhydrous ammonia (82.2% N) decreased by 5% to 12.3 Mt of contained N compared with a revised figure of 12.9 Mt in 1999 (table 1). Of the total production, 88% was for use as a fertilizer; the remaining 12% was used in other chemical and industrial sectors (table 2). Because a significant portion of the ammonia production was estimated, production figures reported by the U.S. Census Bureau were probably high; significant declines in production occurred, especially during the fourth quarter of 2000, because of capacity reductions, which may not have been accounted for in the census figures.

The United States remained the world's second largest producer and consumer of elemental and fixed types of nitrogen following China. In declining order, urea, ammonium nitrate, ammonium phosphates (DAP, monoammonium phosphate, and other ammonium phosphates), nitric acid, and ammonium sulfate were the major downstream products produced from ammonia in the United States. Their combined production was 10.5 Mt of contained N, with urea accounting for about 30% of the production (table 3). Of the urea produced in the United States in 2000, 65% was used for UAN production, 22% was consumed in granular form, 11% was consumed in prill form, and 12% was consumed in feedstock for such other uses as melamine production.

Ammonia producers in the United States operated at about

Digitized by Google

70% of design capacity; this percentage includes capacities at plants that operated during any part of 2000. Excluding the plants that permanently closed during 2000, more than 55% of total U.S. ammonia production capacity was concentrated in the States of Louisiana (33%), Oklahoma (13%), and Texas (9%), owing to large indigenous reserves of feedstock natural gas. Farmland Industries Inc., Terra Industries Inc., PCS Nitrogen Inc., Agrium Inc., CF Industries Inc., and Mississippi Chemical Corp., in declining order, accounted for 73% of total U.S. ammonia capacity (table 4).

Skyrocketing natural gas prices in the second half of 2000 led to temporary closures of much of the U.S. nitrogen capacity. By the end of 2000, the Henry Hub spot price for natural gas had reached more than $10 per million British thermal units. Much of this rapid price increase occurred in the last 3 months of the year; at the end of October, the price was about $4.50 per million British thermal unit, and by the end of November, it was $6.50 per million British thermal unit (U.S. Energy Information Administration, February 5, 2001, Natural gas weekly market update, accessed May 14, 2001, via URL http://www.eia.doe.gov). In some instances, it became more profitable for the operating companies to sell their natural gas futures contracts than to produce and sell nitrogen products. By yearend, about one-half of the U.S. nitrogen production capacity was shut down (Green Markets, 2000i). In addition to regular maintenance turnaround closings, companies began closing capacity in June in response to higher natural gas prices.

At yearend, the following U.S. ammonia plants were closed because of market conditions: Agrium—Finley, WA; Coastal Corp.—St. Helen's, OR, and Cheyenne, WY; Farmland—Pollock, LA; Koch Nitrogen Co.—Sterlington, LA; Royster-Clark Inc.—East Dubuque, IL; and Terra Industries—Beaumont, TX. The following ammonia plants were partially closed because of market conditions: Agrium—Borger, TX [135,000 metric tons per year (t/yr)]; CF Industries—Donaldsonville, LA (762,000 t/yr); and PCS Nitrogen—Augusta, GA (195,000 t/yr), Geismar, LA (95,000 t/yr), and Lima, OH (112,000 t/yr). In addition, many associated urea and UAN production plants were closed without sufficient ammonia feedstock (Fertilizer Markets News Update, 2000).

In January, Agrium signed an agreement with Unocal Corp. to purchase its nitrogen-based production and distribution businesses for an estimated $398 million. Because of market concentration concerns, the U.S. Federal Trade Commission (FTC) investigated the purchase. As a result, the FTC required Agrium to divest the Unocal deepwater terminal near Portland, OR, part of its upriver terminal in central Washington (Hedges), which contains urea storage capacity, and the leases on three UAN terminals, including one with deepwater access. These assets were sold to J.R. Simplot Co. (U.S. Federal Trade Commission, September 29, 2000, FTC clears Agrium, Inc.'s acquisition of Unocal, accessed May 14, 2001, via URL http://www.ftc.gov). The acquisition was finalized in October and included an ammonia-urea complex in Kenai, AK; an ammonia complex in Finley (Kennewick), WA, which also produced ammonium nitrate, nitric acid, and UAN solutions; and storage facilities and terminals in Kennewick and West Sacramento, CA (Green Markets, 2000a).

Also in January, Coastal announced that it would be acquired by El Paso Energy Corp. The total value of the transaction was approximately $16 billion, including $6 billion of assumed debt and preferred equity. The merger was not completed until January 2001, after FTC approval. As part of the FTC approval, the company agreed to divest its ownership in five pipeline systems and certain offshore assets. The revenue from these sales was expected to be used to pay down some debt (El Paso Corp., January 29, 2001, El Paso Energy completes merger with Coastal, creating the world's leading natural gas company, accessed May 14, 2001, via URL http://www.epenergy.com). Coastal, through its subsidiaries, owned three ammonia plants in Cheyenne, WY, Freeport, TX, and St. Helens, OR, with a total capacity of 471,000 t/yr; the ammonia and nitrogen fertilizer assets were only a small portion of Coastal's holdings.

Farmland announced that it would sell its Coffeyville, KS, oil refinery but retain ownership of the adjacent ammonia and UAN plants. The company opened its nitrogen complex, which uses petroleum coke as a raw material, in September and was running the operation in a start-up mode for the remainder of the year (Green Markets, 2000d).

In April, Mississippi Chemical announced it had signed a letter of intent to purchase a 227,000-t/yr granular urea production facility in Faustina, LA, from IMC-Agrico Co. No purchase price was disclosed. Mississippi Chemical planned to operate the plant in conjunction with its ammonia/urea complex located approximately 1.6 kilometers (km) away in Donaldsonville, LA. IMC Global Inc., one of the partners in IMC-Agrico, previously had announced plans to exit the urea business and other noncore product lines as part of its restructuring program launched in December 1998. IMC had stopped production of urea at its Faustina facility in the summer of 1999, but the 508,000-t/yr ammonia plant would continue to supply ammonia as a raw material for use in IMC-Agrico's production of concentrated phosphate products at the same location (Green Markets, 2000g).

Two separate explosions idled parts of two plants for nearly one-half of 2000. On May 24, an explosion at CF Industries' Donaldsonville, LA, ammonia plant killed two workers and hospitalized nine others (ABC News, May 25, 2000, Plant explosion, accessed May 25, 2000, at URL http://abcnews.go.com/sections/us/DailyNews/ammoniaplant000525.html). Because of this, the company's #3 unit was closed for the remainder of 2000, and portions of other units also were closed for most of the remainder of the year because of collateral damage. A July 14 explosion in the ammonia unit at Farmland's Lawrence, KS, ammonia-UAN complex that caused minor damage shut down the plant for a short period. Because of the fire, the company performed a complete turnaround on the plant, and it was brought back on-stream in November (Green Markets, 2000c).

Willard Grain & Feed Inc., operating as Wil-Grow Fertilizer Co., announced that it would liquidate all of the company assets and cease business in February. The company operated ammonia, ammonium nitrate, and UAN production facilities at Pryor, OK; these facilities had been idle since the end of 1999 (Green Markets, 2000k).

In June, Borden Chemical & Plastics L.P. announced that it would close and scrap its ammonia and granular urea complex in Geismar, LA. The company cited a decline in nitrogen values and increasing cost of natural gas feedstock as part of its reason to close the operation (Fertilizer Markets, 2000b).

LaRoche Industries Inc. filed for chapter 11 bankruptcy in May. At the time of the filing, LaRoche estimated that it had more than 1,000 creditors, with Cytec Industries Inc., its equal partner in the Avondale Ammonia Co. joint venture, as the

Digitized by Google

fourth largest. In August, LaRoche announced the sale of its ammonium nitrate facilities in Alabama, Missouri, Illinois, and Utah to Orica LLC, a unit of Orica Ltd., an international manufacturer and distributor of explosives. After the U.S. Bankruptcy Court in Delaware approved the sales, Orica then sold the Cherokee, AL, and Crystal City, MO, facilities to LSB Industries Inc., which planned to operate these facilities under its El Dorado Chemical Co. subsidiary; these facilities included a 159,000-t/yr ammonia plant in Cherokee (Green Markets, 2000f). In April 2001, the Court approved LaRoche's settlement with Cytec in which Cytec will take over total ownership of the Avondale Ammonia plant for $800,000 (Green Markets, 2001).

Environment

The ammonium and nitrate forms of N are highly soluble in water and are readily available for crop plant uptake. Ammonium is held by soil particles and, therefore, is not subject to movement down through the soil during periods of rainfall or irrigation. Nitrates, however, do move downward with soil water. This leaching process can lead to nitrate accumulation in ground water. As soils are warmed during the growing season, the ammonium form of nitrogen is subject to conversion to nitrate in a process called nitrification. Most of the ammonium not used by the crop is eventually converted to nitrate. Nitrogen stabilizers and nitrification inhibitors can slow the conversion of soil ammonium to nitrate. Best management practices to increase nitrogen use efficiency and to reduce nitrate leaching include application of fertilizer close to the time of actual crop use, multiple applications, terracing, grass waterways, and strip cropping.

Hypoxia in the Gulf of Mexico recently has become a controversial environmental concern for the fertilizer industry and an issue that spawned significant research efforts to determine its cause. "Hypoxia in the Gulf of Mexico" refers to an area along the Louisiana-Texas coast in which water near the bottom of the gulf contains less than 2 parts per million of dissolved oxygen. Hypoxia can cause stress or death in bottom-dwelling organisms that cannot move out of the hypoxic zone. Some studies postulated that nitrate runoff from fertilizers is the principal cause of hypoxia, while others cited other causes for the hypoxic zone.

U.S. Geological Survey (USGS) study results published in 2000 supported previous findings that most of the nitrogen pollution delivered to the Gulf of Mexico by the Mississippi River originates far upstream in the upper Midwest and Ohio Valley States. But this study also found that within these regions there were large differences in the percentage of nitrogen reaching the gulf, depending on the relation of the location of nitrogen sources to streams of different sizes in the watershed. The study found that the rates of nitrogen reaching the gulf from upstream areas near large rivers in such States as Ohio and Minnesota were much higher than those in neighboring areas near small streams. Moreover, areas near large rivers in these same States, located more than 2,400 km from the gulf, also deliver more nitrogen to the Gulf than areas near small streams in the states of Mississippi and Arkansas, located only a few hundred kilometers from the Gulf. This study found that nitrogen pollution was naturally removed from water much more rapidly in small streams than in large rivers. As a result, nitrogen delivery from point and nonpoint sources in a stream drainage basin was not simply a function of the distance between the gulf and the nitrogen source, but a function of the amount of time the nitrogen traveled through small streams (U.S. Geological Survey, 2000, Percentage of stream nitrogen reaching the Gulf of Mexico, accessed May 15, 2001, at URL http://www.usgs.gov/themes/nature.html). The data supporting these conclusions also has been published as a map. Information on additional USGS involvement in hypoxia research is available at URL http://toxics.usgs.gov/highlights/hypoxia.html.

A group of scientists from Federal agencies and academic institutions completed its report "Hypoxia in the Northern Gulf of Mexico," which was released in May 2000. In this assessment, a national model of the agriculture sector was used to examine many of the economic effects and the changes in nitrogen loading under various scenarios. Reducing nitrogen loss at the edge of the field by 20% through a combination of economically optimal improvements in farming practices would be expected to cost producers and consumers about $0.40 per pound of nitrogen reduction. Other measures to reduce nitrogen loads to rivers and streams, such as reducing urban point and nonpoint sources and atmospheric deposition, could provide important contributions in some instances; average costs of reducing point sources and atmospheric deposition were estimated to be between $5 and $50 per pound. Increasing the acreage of wetlands and vegetated riparian buffers within the basin would enhance denitrification (a process that removes nitrogen from the system), increase nitrogen retention, and decrease the amount of nitrogen entering streams and rivers. Model analyses demonstrated that the most effective use of restored and created wetlands would be in watersheds that discharge high quantities of nitrogen. At typical denitrification rates for flow-through wetlands, more than 2 million hectares of wetlands would reduce nitrogen load to the gulf by 20% and would cost an estimated $4.05 per pound of nitrogen denitrified. An estimated 7.7 million hectares of additional riparian buffers would be needed to reduce nitrogen load to the gulf by the same amount (U.S. Department of Commerce, National Oceanic and Atmospheric Administration, May 2000, Hypoxia in the northern Gulf of Mexico, accessed November 7, 2000, at URL http://www.nos.noaa.gov/products/pubs_hypox.html).

On October 11, Federal and State officials agreed on a $1 billion per year plan to revive as much as 30% of the hypoxic zone in the Gulf of Mexico by 2015. Under the plan, more money would go to programs that reduce excess nutrients in streams and rivers feeding into the Mississippi, which drains 40% of the continental United States. These programs would cut fertilizer use on farms, establish wetlands and buffer strips near streams to soak up excess nitrogen, and reduce discharges from sewage treatment plants. The plan also called for funding scientific efforts to track the flow of nitrogen (U.S. Department of Commerce, National Oceanic and Atmospheric Administration, October 12, 2000, Agreement to shrink dead zone, accessed May 17, 2001, at URL http://www.nos.noaa.gov/products/pubs_hypox.html#update).

A report prepared by the National Research Council of the National Academy of Sciences stated that the Federal Government—along with State and local agencies—should develop a comprehensive regulatory solution to combat nitrogen and phosphorous runoff from agricultural fields, which was causing serious environmental damage along the Atlantic and Pacific coastlines. The committee that prepared the reports said

Digitized by Google

that a national strategy should strive to reduce the number of severely damaged coastal areas by 25% by 2020 and to ensure that no other areas become affected. Initiatives that were identified by the committee to address the problem included expanding monitoring and assessment programs, exerting Federal leadership on issues spanning multiple jurisdictions or threatening federally protected natural resources, eliminating overlap and gaps among existing and proposed Federal legislation, providing data and technical assistance to local coastal authorities, and developing a classification scheme to provide better information on the likelihood that excess nutrients will damage coastal areas (Green Markets, 2000h).

Nutrient runoff also was hypothesized to cause deterioration of the coral reefs in the Florida Keys. According to a report prepared by scientists from the University of Miami, nutrients in runoff from the Everglades agricultural area were generating algal blooms, which in turn have killed sponges, increased turbidity, reduced the light available to seagrasses, and altered the entire food web of Florida Bay. The research also has shown that this nutrient- and algae-rich water was transported into the Florida Keys coral reef tract, where water quality has declined (Larry Brand, 2000, An evaluation of the scientific basis for "restoring" Florida Bay by increasing freshwater runoff from the Everglades, accessed May 17, 2001, via URL http://www.reefrelief.org/main.html).

Economic and environmental effects of alternative environmental policies were analyzed using the U.S. Regional Agricultural Sector Model developed by the U.S. Department of Agriculture's (USDA) Economic Research Service. The analysis covered policy effects on most major agricultural commodities. A goal of 10% reduction in nitrogen releases from agriculture was used to illustrate the effects of a small change in nitrogen releases on production and trade. To reduce nitrogen releases by 10%, four alternative generic policy approaches were evaluated: (1) a "green payment" that producers would receive from the Government to compensate for lower returns resulting from lower crop yields caused by reduced fertilizer use; (2) regulations to reduce per-acre nitrogen use; (3) a tax on nitrogen fertilizer; and (4) buffer strips and other land retirement to intercept field runoff and reduce nitrogen fertilizer use. Among the first three policies, a green payment policy would achieve the environmental goal with the least market-price escalation. A green payment approach also would generate the smallest consumer costs and the greatest producer benefits, but it also would involve the greatest Government cost and would result in the largest increase in soil erosion. In contrast, a land retirement policy to achieve the same nitrogen loss reduction would have export-reducing effects almost six times that of a green payment policy, with the largest costs to consumers. Producer benefits in the land retirement scenario were second only to green payments, and the reduction in soil erosion was the greatest of any scenario. (Agricultural Outlook, 2000).

Consumption

In 2000, apparent consumption of ammonia decreased by 5% to 15.4 Mt of contained N. Apparent consumption is calculated as the production plus imports minus exports, adjusted to reflect any changes in stocks.

Consumption of nitrogen fertilizers in the United States for the 2000 crop year (ending June 30, 2000) is listed in table 5. Consumption of 11.2 Mt of contained N was about 2% less than that in 1999. Anhydrous ammonia was the principal fertilizer product, representing 30% of fertilizer consumption. Of the single-nutrient fertilizers, only consumption of urea and ammonium sulfates increased from that in the 1999 crop year.

Other uses of ammonia are in the production of amines, cyanides, and methyl methacrylate polymers (plexiglass); in liquid household and industrial cleaners; in industrial stack-gas scrubbing; in pulp and paper products; in industrial refrigeration; in metallurgy; and as a propellant in vehicular air bags (Nitrogen & Methanol, 2000b).

Urea and UAN solutions constituted 42% of fertilizer consumption during the 2000 crop season. Urea is typically 45.9% N, and UAN solutions are typically 29.8% to 29.9% N. In the industrial sector, urea is used extensively as a protein supplement in ruminant animal feeds, in the production of urea-formaldehyde adhesives, and in the synthesis of plastics and resins.

Ammonium nitrate was used primarily in solid and liquid fertilizers, in industrial explosives, and as blasting agents. After World War II, ammonium nitrate became the leading solid nitrogen fertilizer in the United States and worldwide and remained so until about 1975 when its use was surpassed by synthetic urea. Ammonium nitrate containing 33.9% N constituted 5% of 2000 nitrogen fertilizer consumption.

Ammonium sulfate was used mostly as a fertilizer material, valued for its nitrogen content (21.2% N) and its readily available sulfur content (24.3% sulfur). It is commonly produced as a byproduct of caprolactam production, an intermediate in nylon manufacture. Since the introduction of ammonium nitrate and urea as fertilizer materials, the relative importance of ammonium sulfate worldwide has steadily decreased. In the 2000 crop year, fertilizer consumption of ammonium sulfate, based on nitrogen content, was 2% of the total nitrogen-based fertilizer market. Nonfertilizer uses of ammonium sulfate include food processing, fire control, tanning, and cattle feed.

Nitric acid production is listed in table 3. Nitric acid is used in salt formation reactions to produce metal nitrates and in metal degreasing, treating, and pickling for the graphic and galvanic industries. Nitration reactions with benzene, phenol, and toluene produce dyestuffs, pharmaceutical products, trinitrotoluene explosives, and disinfectants. Esterification reactions with glycol, glycerol, and cellulose produce nitroglycerine explosives (dynamite), celluloid, and nitrocellulose lacquers. Oxidation reactions with toluene, p-xylene, and cyclohexanone produce polyurethanes and polyester fibers (nylon).

Elemental nitrogen is used extensively by the electronics, metals, food, and aerospace industries because of its inert and cryogenic properties. Nitrogen can be used to prevent fires and explosions, as a purging agent for cleaning and processing equipment, and as a controlling atmosphere for annealing and heat treating and other metal preparation processes where oxygenation is a concern.

Stocks

Stocks of ammonia in 2000 were 1.12 Mt, an increase of 12% from those at the end of 1999, according to data published by The Fertilizer Institute (table 6). The U.S. Census Bureau reported ending stocks of ammonia to be 420,000 metric tons

Digitized by Google

(t), which was a significant difference from The Fertilizer Institute data. In addition, there were no reported census data for 1999 with which to compare this figure because the 1999 data were withheld. Although the USGS traditionally has used census data in calculating apparent consumption, the calculation was computed using The Fertilizer Institute data to minimize irregularities caused by continually switching data series.

Transportation

Ammonia was transported by refrigerated barge, rail, pipeline, and truck. Three companies serve 11 States with 4,900 km of pipelines, with 4,800 km of river barge transport, and by rail and truck used primarily for interstate or local delivery.

Koch Industries Inc. operated the Gulf-Central ammonia pipeline from the Gulf of Mexico (Louisiana) to the Midwest as far north as Iowa, spanning 3,070 km, and to the east to Huntington, OH. The annual capacity of this pipeline was about 2 Mt, with a storage capacity of more than 1 Mt.

CF Industries and Cargill Fertilizer Inc. jointly operated the 135-km long Tampa Bay pipeline (TBP) system. TBP moved nitrogen compounds and ammonium phosphate for fertilizer producers in Hillsborough and Polk Counties, FL.

The pipelines of Williams Companies Inc. and its subsidiary Mid-America Pipeline System extend from Borger in northern Texas to Mankato in southern Minnesota, covering 1,700 km. The pipelines have an annual capacity of more than 1 Mt and about 500,000 t of ammonia storage capacity. In 2000, Williams formed a wholly owned subsidiary, Williams Energy Partners L.P., to acquire, own, and operate a diversified portfolio of energy assets. This partnership includes Williams' ammonia pipeline and distribution facilities. In October, Williams Energy Partners filed with the Securities and Exchange Commission to register for an initial public offering of stock, which was begun in February 2001 (The Williams Companies Inc., October 30, 2000, Williams Energy Partners L.P. files S-1, accessed November 8, 2000, at URL http://www.williams.com/news/newsreleases/rel618.html).

Capacities for trucks and railcars are usually 20 t and 100 t, respectively. Depending on the product loaded and the volume of the container, barges can accommodate from 400 t to 2,000 t.

Ammonium nitrate is transported by rail, road, and water, but its transportation on U.S. navigable waterways is restricted. Urea is shipped either in bulk or as bagged material.

Prices

Although the individual price curves were slightly different, all the nitrogen prices (ammonia, ammonium nitrate, ammonium sulfate, and urea) reached their highest price of the year at yearend (table 7). Ammonia prices climbed throughout most of the year (figure 1). After a steep climb during the spring planting season to $176 per short ton from $117 per short ton, the price stabilized, then reacted to the escalation in natural gas prices to increase to $230 per short ton by yearend. Granular urea prices rose early in the year to $148 per short ton from $110 per short ton (figure 2), then dropped slightly. After a price spike at midyear, the price leveled off until the very end of 2000 when it, too, reacted to the increased natural gas price. At yearend, the granular urea price was $160 per short ton. The average granular Gulf Coast urea price for the year was about $143 per short ton, more than 50% higher than the 1999 average price. The average ammonia price was $169 per short ton.

Ammonium nitrate prices (figure 3) showed a similar trend to that of urea, rising early in the year, declining, rising again at midyear, then leveling off until the very end of 2000 when they reached their high for the year at $145 per short ton. Ammonium sulfate prices also rose at the beginning of 2000, leveled off at about $122 per short ton, then rose to reach $133 per short ton at yearend (figure 4).

Foreign Trade

Ammonia exports increased by about 18% from those in 1999 (table 8); much of this increase was reflected in increased exports to the Republic of Korea, which remained the principal destination, accounting for 80% of total U.S. exports of ammonia. Most of the material shipped to the Republic of Korea was produced at the Agrium plant in Alaska.

Imports of anhydrous ammonia were essentially the same as those in 1999 (table 9). Trinidad and Tobago (51%), Canada (22%), and Russia (19%) were the primary sources. Tables 10 and 11 list trade of other nitrogen materials and include information on principal source or destination countries.

World Review

Anhydrous ammonia and other nitrogen materials were produced in more than 80 countries. Global ammonia production in 2000 increased by about 2% from that of 1999 (table 12). In 2000, total ammonia production was 109 Mt contained N, according to data reported to the USGS. China, with 26% of this total, was the largest world producer of ammonia. Asia contributed 44% of total world ammonia production, and the United States and Canada represented 15% of the global total. Countries in the former U.S.S.R. produced 13% of the total; Western Europe, 10%; the Middle East, 7%; Latin America, 5%; and Africa, Eastern Europe, and Oceania contributed the remaining 6%.

In 2000, world ammonia exports increased by 6% to 12.7 Mt of contained N compared with those of 1999. Russia (19%), Trinidad and Tobago (19%), Ukraine (10%), and Canada (7%) accounted for 55% of the world total. The United States imported 33% of global ammonia trade, followed by Western Europe (27%) and Asia (20%) (International Fertilizer Industry Association, 2001a, p. 1-11).

In 2000, world urea production increased slightly to 49.4 Mt of contained N. Urea exports increased by nearly 9% to 12.0 Mt of contained N. China and India, the two largest producing countries, accounted for 47% of world production; production in China increased by about 2% and production in India decreased by 1% compared with those of 1999. The United States and Canada produced about 11% of the total. Exports from most geographic areas increased, with the exception of an 8% decrease from North America and a 27% decrease from Latin America. The Middle East exported the largest quantity of urea with 26% of the total. Russia and Ukraine together also accounted for 26% of total exports, Asia for 13%, Canada and the United States for 10%, Western Europe for 8%, Eastern Europe for 7%, and China and Latin America for 4% each. Latin America accounted for 21% of global urea imports, Western Europe for 18%, North America for 17%, and Asia for 16% (International Fertilizer Industry Association, 2001b, p. 1-

Digitized by Google

14).

Algeria.—ASMIDAL Group, its trading partner Transammonia Inc., and the German engineering firm Ferrostaal AG signed a memorandum of understanding (MOU) to build a 600,000-t/yr joint-venture ammonia plant. The new facility was expected to be sited in Arzew near two existing ammonia units with a combined capacity of about 550,000 t/yr. Estimated project cost was $370 million, and the product would likely be exported to nearby fertilizer and caprolactam producers on the Spanish Mediterranean coast. The joint-venture partners did not disclose how the equity would be divided or the potential timetable for plant construction (Fertilizer Week, 2000a).

Argentina.— In May, Profertil S.A., the joint venture between Agrium and Repsol YPF S.A., began ammonia trials at its new 1.1-million-metric-ton-per-year (Mt/yr) ammonia-urea complex in Bahia Blanca. A fire at the ammonia plant in July delayed full commissioning of the ammonia section until October, which in turn delayed the start-up of the urea section. The commissioning of the granular urea section, originally scheduled for the second half of 2000, was delayed further because of ammonia leaks and vents that occurred during start-up. By yearend, Profertil decided to install ammonia flare stacks at the complex as protection against future ammonia leaks or vents (Fertilizer Week, 2000v). The urea plant began production in January 2001.

Australia.—Wesfarmers CSBP began commissioning its new $90 million, 650-metric-ton-per-day (t/d) ammonia plant in April. The plant was scheduled to be commissioned in September 1999, but building delays postponed the start-up. The new plant uses Haldor-Topsøe technology and replaced a 300-t/d unit that was closed in August 1999. The additional production from the new plant would also replace ammonia that had been imported from Qatar (Fertilizer Week, 2000c). Wesfarmers used the ammonia as feedstock for ammonium nitrate production, gold extraction, and nickel refining.

Queensland Fertilizer Assets Ltd., Krupp Uhde, a unit of ThyssenKrupp AG of Germany, and Devco International Co. of the United States, signed an MOU to develop a nitrogen fertilizer complex near Pickanjinnie, Queensland. The proposed plant, which was scheduled to be completed by 2003, was expected to have the capacity to produce 330,000 t/yr of ammonia, 330,000 t/yr of urea, and 150,000 t/yr of low-density ammonium nitrate. Krupp Uhde will use its own licensed technology for the production units (Fertilizer Week, 2000z).

Plenty River Corp. and India's Chambal Fertilizers and Chemicals Ltd. terminated the MOU that they signed in 1999 relating to Plenty River's proposed ammonia-urea complex in Western Australia. As part of the MOU, Chambal Fertilizers and Chemicals would be brought into the project as a 50%-equity participant upon completion of a positive feasibility study (Fertilizer Markets, 2000f). Plenty River was seeking a new participant to take Chambal Fertilizers and Chemicals' 50% share. The other equity partners in the project were Snamprogetti S.p.A. of Italy (15%) and Theiss Pty. Ltd. (5%); Plenty River maintains a 30% equity. Right after the MOU was dissolved, Queensland Fertilizer Assets signed a 15-year offtake contract with Helm Düngemittel of Germany GmbH, an international marketing company. Under this agreement, total production of ammonia and urea would be sold to Helm Düngemittel under a 15-year take-or-pay contract. The plant was expected to produce approximately 760,000 t/yr of granular urea with 190,000 t/yr of excess salable ammonia. Construction was scheduled to begin in 2001 with commissioning of the plant in 2004 (Fertilizer Week, 2000u).

Bangladesh.—In May, Bangladesh Chemical Industries Corp. and China's Huanqui Chemical Engineering Co. signed an MOU to conduct a feasibility study for a 560,000-t/yr urea plant in northwestern Bangladesh. Although several sites were under consideration, the most probable site was Sirajganj (Nitrogen & Methanol, 2000a).

Brazil.—After a 3-month shutdown beginning in September, Petróleo Brasileiro S.A. (Petrobras) increased capacity at its ammonia-urea complex in Camacari by about 50%. Total production capacity after the revamp was 495,000 t/yr of ammonia and 500,000 t/yr of urea. Petrobras exported most of its surplus ammonia through a term contract with Transammonia (Fertilizer Week, 2000s).

Bulgaria.—In June, a consortium of a management buyout team and one of its marketing partners purchased 51% of Neochim S.A. for $100,000. After the buyout, the ownership of the plant was shared among the Bulgarian company Evrofert S.A. (the buyout team) (39%), the Lebanese company Karimex Chemicals International S.A. (the marketing partner) (12%), and the Bulgarian Government (24%). Small portions were owned by various funds and private individuals. The new owners planned to invest $5.5 million over 5 years to improve the plant. Production capacity at the plant was estimated to be 410,000 t/yr of ammonia and 630,000 t/yr of ammonium nitrate, but the plant had been operating at only about 40% of the total (Fertilizer Week, 2000o). As part of the buyout, the company reached an agreement with the country's natural gas supplier to extend Neochim's debt repayment period until April 30, 2001.

In November, Bulgaria's Council of Ministers announced an increase in the duty on ammonium nitrate to 40% from 25%; this duty increase was aimed at protecting domestic producers from imports of ammonium nitrate from Georgia, Romania, Russia, and Ukraine. The duty increase was requested by producers in June when gas prices began to climb. The Government started an antidumping duty investigation to parallel the increase in import duties (Fertilizer Week, 2000b.).

Canada.—The sharp increase in natural gas prices that resulted in closures at many U.S. ammonia facilities also had the same effect on many plants in Canada. At yearend, Agrium had closed about 651,000 t/yr of its ammonia capacity in Alberta because of market conditions. This represented about 27% of the company's total production capacity in Alberta (Fertilizer Markets News Update, 2000).

Chile.—After Potash Corp. of Saskatchewan (PCS) purchased the Yumbes nitrate operation in 1999, it renamed the operation PCS Yumbes, and the company began producing nitrates from the deposit in August 2000. The first material to be produced was potassium nitrate. Eventually, the company planned to produce about 300,000 t/yr of nitrates, of which about 265,000 t/yr was expected to be potassium nitrate, and the remaining 35,000 t/yr would be sodium nitrate. For domestic sales, PCS has entered into a marketing agreement with Cargill Inc. to serve Chilean fertilizer and industrial-grade nitrates markets (Fertilizer Week, 2000r).

Sociedad Quimica y Minera de Chile S.A. (SQM) brought its new 160,000-t/yr potassium nitrate plant on-stream at the end of August. As part of the joint-venture agreement that was signed in 1998 between SQM and Norsk Hydro A/S, SQM retained the majority stake in the plant, and by selling nitrates, Norsk Hydro had the opportunity to increase its product range in Europe

Digitized by Google

(Fertilizer Week, 2000aa).

A third potassium nitrate plant in Chile was scheduled to begin production by yearend. Compania de Salitre y Yodo S.A. (Cosayach) expected to begin production at its 200,000-t/yr operation near Pozo Almonte. Although potassium nitrate would be the principal product, Cosayach also planned to produce sodium nitrate and iodine (Fertilizer Markets, 2000e).

China.—Yunnan Yuntianhua Co. and its trading partner China National Chemical Construction Co. signed a licensing contract with the Dutch firm Stamicarbon bv to debottleneck and upgrade its urea plant in Shuifu, Yunnan Province. The upgrade was expected to be completed in 2002 and would increase the plant's capacity to about 860,000 t/yr from 535,000 t/yr. In addition to increasing capacity, the revamp was expected to help improve energy consumption (Fertilizer International, 2000c).

China National Offshore Oil Corp. announced that it would construct an ammonia-granular urea plant in Dongfang City, Hainan Province. Proposed plant capacity was 450,000 t/yr of ammonia and 800,000 t/yr of urea. Construction of the $362 million plant was scheduled to begin in 2001, with completion scheduled for 2003 (Fertilizer International, 2000c).

Egypt.—By September, Egyptian Fertilizer Co. completed the start-up of its ammonia-urea complex in Ain Sukhna. The new plant could produce 635,000 t/yr of granular urea and an additional 50,000 t/yr of excess ammonia. Egyptian Fertilizer has long-term contracts for 100,000 t/yr of urea each with four international trading firms and two local firms. Although the material would initially be shipped from existing ports to its principal markets in Israel, Jordan, Mauritius, and South Africa, Egyptian Fertilizer planned to construct a bulk handling terminal by the second quarter of 2001 that would be Egypt's only terminal capable of handling panamax and cape-sized vessels (Fertilizer Week, 2000h).

European Union.—The European Commission (EC) enacted a significant number of antidumping decisions during 2000. In September, the EC established definitive antidumping duties on UAN from Algeria, Belarus, Lithuania, Russia, and Ukraine; these duties will last for 5 years. The duties (in euros per metric ton) were as follows: Algeria, 6.88; Belarus, 17.86; Lithuania, 3.98; Russia, 17.80 to 20.11, depending on the company; and Ukraine, 26.17. The original complaint, filed by the European Fertilizer Manufacturers Association (EFMA) included UAN from Slovakia, but imports from this country were still being investigated (Fertilizer Markets, 2000d).

In July, the EC imposed 6-month provisional antidumping duties on imports of ammonium nitrate from Poland and Ukraine. For Poland, the duty ranged from 22.61 euros per metric ton to 29.91 euros per metric ton, depending on the producer. For Ukraine, the country-wide duty was 33.25 euros per metric ton. The original investigation included imports from Lithuania; however, the EC found the dumping margin from this country to be minimal and did not establish any provisional duties (Fertilizer Week, 2000k).

In September, the EC also began an interim review of current antidumping duties on imports of ammonium nitrate from Russia. The existing duty of 26.3 euros per metric ton expired in August, and EFMA asked for a review in March (Fertilizer Week, 2000j). In October, the EC began an antidumping investigation into imports of urea from Belarus, Bulgaria, Croatia, Egypt, Estonia, Libya, Lithuania, Poland, Romania, and Ukraine. The EFMA lodged a complaint in September alleging that volumes and prices of urea from these countries had a damaging effect on the sales and markets shares of its members (Fertilizer Week, 2000g).

India.—In February, the Indian Government announced a 3-year moratorium on all domestic greenfield urea projects and that it could not guarantee that proposals to expand existing units would be protected under the country's retention pricing scheme (RPS). [The RPS ensured project feasibility by allowing an automatic 12% after-tax return on capital investment as soon as new units are commissioned.] This new policy eliminated proposals for new projects that were recently approved—Indian Farmers Fertiliser Cooperative Ltd.'s (IFFCO) 768,000-t/yr new plant at Nellore, Krishak Bharati Co-operative's (Kribhco) 768,000-t/yr expansions at Hazira and Gorakhpur, and Rashtriya Chemicals & Fertilizers Ltd.'s 726,000-t/yr expansion at its Thal complex (Fertilizer Week, 2000e).

Indonesia.—PT Kaltim Parna Industri, a joint venture between Japanese firms Mitsubishi Corp. (55%) and Asahi Chemical Industry Co. Ltd. (10%) and the Indonesian companies PT Parna Raja (25%) and PT Pupuk Kalimantan Timur (Kaltim) (10%), started construction of a $240 million ammonia plant in Bontang, East Kalimantan. The project, which had been postponed since 1997, was scheduled for completion in 2002. Capacity at the plant was projected to be 495,000 t/yr. Natural gas for the plant will be supplied by the State-owned natural gas company under a 20-year contract. Output from the plant was expected to be exported primarily to China, Japan, the Philippines, and Thailand (Fertilizer Week, 2000n). Kaltim Pasifik Amoniak began production at its 660,000-t/yr ammonia plant in Bontang in March, and its first export sales were completed in April.

PT Pupuk Sriwidjaja, the holding company for Indonesia's State-owned fertilizer producers Kaltim, PT Petrokimia Gresik, PT Pupuk Kujang, and PT Pupuk Iskandar Muda (PIM), delayed three fertilizer projects pending clarification of the Government's privatization plans. The three projects were Kujang's 570,000-t/yr urea plant at Cikampek, Java; Kaltim's 570,000-t/yr urea plant at Bontang, East Kalimantan; and PIM's ammonia-urea complex at Lhokseumawe, Aceh (Fertilizer International, 2000a).

Israel.—Haifa Chemicals Ltd. completed a debottlenecking and expansion project that doubled the company's potassium nitrate production capacity to 100,000 t/yr. Haifa Chemicals marketed the potassium nitrate for agricultural and industrial applications (Fertilizer International, 2000b).

Malaysia.—Production at Petronas Ammonia Sdn. Bhd.'s new 450,000-t/yr ammonia plant at Kerteh began in October. Most of the production was destined for export. Mitsubishi and Mitsui & Co. Ltd. signed MOU's with Petronas for the offtake of the ammonia, but final agreements were not completed by yearend (Fertilizer Week, 2000t).

Mexico.—In May 1999, Agro Nitrogenados de Mexico S.A. de C.V. (Agromex) had stopped production of urea because Petroquimica Cosoleacaque S.A. de C.V. stopped supplying ammonia to the plant when Agromex's parent company filed for bankruptcy. Although press reports indicated that there was an agreement on feedstock supplies among the Energy Ministry, Pemex, and domestic fertilizer producers that would allow the restart of Agromex's 1.1 Mt/yr urea production capacity in February, the agreement fell through (Fertilizer Week, 2000p).

Because of the stoppage in domestic production, imports of

Digitized by Google

urea into Mexico increased significantly in the past 2 years. Compared to imports of 340,000 t in 1998, urea imports increased to 495,000 t in 1999 and to 561,000 t in 2000. Much of these imports were supplied by Russia (55% in 2000) (International Fertilizer Industry Association, 2001b, p. 7L-7R). Because of the increased imports from Russia, Agromex had petitioned Mexico's customs agency to investigate dumping of imports from Russia and the United States. The investigation began in 1999, and in April 2000, the authorities determined that Mexican urea production was not harmed by imports of Russian and United States urea. The Government determined that Agromex could not start its urea plants, because the high cost of domestically produced ammonia did not allow domestic urea to compete with cheaper imports. As a result of this determination, Agromex decided to sue the Government claiming that imports improperly lowered urea values. Agromex wanted Mexican authorities to convene a trilateral commission under the auspices of the North American Free Trade Agreement to examine the determination (Fertilizer Markets, 2000a).

Netherlands.—Kemira Agro Oy announced that it would close its nitrogen operations in Rozenberg as part of its restructuring program. The Roenberg operations included capacities of 550,000 t/yr of ammonia and 230,000 t/yr of urea, as well as production capacity of UAN and calcium ammonium nitrate. High natural gas prices and persistent oversupply in the European nitrogen fertilizer markets were cited as additional reasons for closure (Fertilizer Week, 2000m).

Oman.—In June, the Indian Government signed an offtake agreement for the production from the proposed Oman-India Fertilizer Co. ammonia-urea joint venture. Under the terms of the agreement, the Government would honor a 25-year take-or-pay contract for 1.6 Mt/yr of urea from the plant. Any surplus ammonia that would be generated was expected to be taken by IFFCO, one of the joint-venture partners (25%), under a 15-year agreement (Fertilizer Week, 2000d). The new plant was expected to be completed in 2003, with a capacity of 1.67 Mt/yr of granular urea and 1.2 Mt/yr of ammonia. Kribhco (25%) and Oman Oil Co.(50%) were the other partners in the joint venture.

Suhail Bahwan Group announced that it would construct an ammonia-urea complex in the Sohar industrial area. The new plant would have a design capacity of 2,000 t/d of ammonia and 2,600 t/d of granular urea. The estimated cost of the plant was between $450 million and $500 million; 30% of this cost was expected to be funded by Sheikh Suhail Salem Bahwan and the remaining 70% was expected to be financed. Construction was scheduled to begin by mid-2001, after a contractor is selected, and would be completed by 2004 (Fertilizer Week, 2000x).

Pakistan.—In June, Pakistan's Privatisation Commission invited bids for a controlling stake in the country's largest nitrogen fertilizer producer, Pak-Saudi Fertilizers Ltd. The local government expected to sell its majority holding by early 2001. The plant, in Mairpur Mathelo, could produce 557,000 t/yr of urea and 320,000 t/yr of ammonia. This was the second attempt to privatize the plant. Although the deadline to submit bids originally was in October, the committee extended the deadline by 3 months because of a lack of interest from foreign buyers (Nitrogen & Methanol, 2000c).

Engro Pakistan Chemical Ltd. announced that it would add 100,000 t/yr of capacity to its urea plant in Daharki by 2002. This would bring the total capacity at the plant to 950,000 t/yr. The new capacity was being added to provide material for the company's 100,000-t/yr nitrogen-phosphorus-potassium (NPK) granulation unit under construction at Port Qusim in 2001 (Fertilizer Week, 2000i).

Qatar.—Qatar Fertiliser Co. (Qafco) received approval for its Qafco IV expansion in October. The expansion would increase total capacity at the Umm Said complex to 2.8 Mt/yr of urea, making it one of the largest urea plants in the world. The cost of the expansion was estimated to be $500 million, and bids for plant construction were expected to be finalized by the third quarter of 2001. The expansion was scheduled to be on-stream by mid-2004 and primarily would supply the nearby Indian market (Fertilizer Week, 2000y). Qafco is a 75%-25% joint venture between Qatar General Petroleum Corp. and Norsk Hydro.

Russia.—TogliottiAzot, Russia's largest ammonia and urea producer, announced a plan to build an ammonia terminal that would give it direct access to the Black Sea. The company had been exporting its ammonia via a 2,250-km pipeline that runs to the Ukranian port of Yuzhnyy. Because one-third of the pipeline runs through Ukraine, the Russian ammonia had been subject to tariffs ($23 per metric ton) and restrictions on throughput (1.25 Mt/yr). The proposed ammonia terminal would consist of the construction of ammonia handling facilities near Temryuk, on the Russian coast of the Azov Sea, which flows directly into the Black Sea. This terminal could handle large ammonia vessels and panamax-size ships. The project also would involve transporting ammonia by rail 350 km south from a point on the existing pipeline close to the Russia-Ukraine border and include a new 35-km section of rail line. The project was estimated to cost $200 million, some of which would be offset against the cost of the Ukrainian tariffs and some of which may be financed by the European Bank for Reconstruction and Development (Fertilizer International, 2000d).

Saudi Arabia.—The National Chemical Fertilizer Co., a joint venture between Saudi Arabia Basic Industries Co. (Sabic) and Saudi Arabian Fertilizer Co., announced that it would debottleneck its ammonia plant at ibn al-Baytar to increase capacity to 583,000 t/yr from 500,000 t/yr. The expansion, which was to be completed by Japan's Toyo Engineering Corp. by the first quarter of 2002, would supply some of the feed requirements for Sabic's increase in urea production capacity (Fertilizer Week, 2000w).

South Africa.—Norway's Norsk Hydro acquired 51% of Kynoch Fertilizer Ltd. and, as a result, owned the company in a joint-venture agreement with its former parent AECI Ltd. Through the agreement, Kynoch would produce and market NPK and liquid fertilizers in the South African market. As part of the agreement, Norsk Hydro would supply 250,000 t/yr of plant nutrients, and Kynoch would close its nitrate production plants in South Africa (Industrial Minerals, 2000).

Trinidad and Tobago.—On December 31, 1999, PCS shut two of its four ammonia plants in Point Lisas because of a disagreement with its natural gas supplier, National Gas Co. of Trinidad and Tobago Ltd. A 15-year supply contract expired at the end of 1999, and contract terms suitable to both parties were not agreed upon, which resulted in the closure of 930,000 t/yr of capacity. PCS's two other ammonia plants and its urea plant at the same location, however, were not affected. It was not until the middle of June that the two companies negotiated a gas-supply contract and production at the plants restarted (Fertilizer Week, 2000q).

Digitized by Google

Construction of the $268 million 645,000-t/yr Caribbean Nitrogen Co. Ltd. ammonia plant in Point Lisas began early in 2000. Ferrostaal is responsible for construction of the facility using technology supplied by M.W. Kellogg Corp. The construction time was estimated to be 28 months, and start-up of the facility was scheduled for the last quarter 2002. Debt financing was expected to be provided by Kreditanstalt für Wiederaufbau backed by the German credit insurance agency Hermes. The shareholders of the project were Clico Energy Co. Ltd., U.S.-based Duke Energy Corp., EOG Resources Trinidad Ltd., KBR Development Corp., and Ferrostaal. Even before this plant is completed, Duke Energy was seeking financing for a second 650,000-t/yr plant at the same location. The $300 million to finance the second plant was expected to come from the same companies that financed the first plant. If financing is completed by early 2001, the new plant could be operational by 2004 (Fertilizer Markets, 2000c).

Turkey.—In June, the Turkish Privatisation Administration announced that it would accept bids for the privatization of fertilizer producers Istanbul Gübre Sanayii (Igsas) and Türkiye Gübre Sanayii (Tügsas). Igsas was the country's sole urea producer with four plants totaling 560,000 t/yr of capacity, and Tügsas produced ammonium nitrate, DAP, and compound fertilizers at a number of plants. Although Toros Fertilizer and Chemical Co.'s bid for two of the Igsas units, its port installations, and its distribution network was accepted by the Privatisation Administration, it was rejected by the country's competition authorities in November. Toros was one of the country's largest urea importers, and it was determined that this purchase would limit competition in the urea market. Bids for the Tügsas plants were rejected by the Privatisation Administration (Fertilizer Week, 2000bb).

Ukraine.—Because of its failure to pay an estimated $21.6 million in taxes since it was founded in 1997, Ukrzovnishkhimprom, which controlled the Togliatti-Yuzhnyy ammonia pipeline, would be broken into independent regional companies. The companies would be subsidiaries of newly formed Ukykhimtransammiak and would charge ammonia shippers for transportation and pay taxes to local authorities (Fertilizer Week, 2000cc). The Government also withdrew approval to nitrogen fertilizer producer DneproAzot to build an ammonia pipeline from its plants in Dneprodzerzhinsk to connect to the Togliatti-Yuzhnyy pipeline. The Government said that the funds for the project, which were to be partially supplied by duties from transporting Russian ammonia, should not be used to support a project promoted by a company that belongs to offshore shareholders (Fertilizer Week, 2000f).

United Arab Emirates.—By October, Southern Petrochemical Industries Corp. was approximately 50% finished with its conversion of an ammonia-urea unit to use natural gas rather than naphtha as a feedstock. Projected start-up of the 400,000-t/yr urea plant in Jebel Ali was late 2001, which is almost 3 years later than originally planned. Prolonged negotiations for gas supply agreements and low urea prices were cited as the reasons for the delay (Nitrogen & Methanol, 2000d).

Venezuela.— Fertilizantes Nitrogenados de Venezuela (FertNitro) completed construction of its ammonia-urea complex in Jose in the fourth quarter. The plant was jointly owned by Petroquimica de Venezuela S.A., Koch Nitrogen, Snamprogetti, and Empresas Polar. After start-up in early 2001, FertiNitro will produce over 1.2 Mt of ammonia and 1.5 Mt of urea annually. Much of the plant's output was expected to be destined for North American markets (Fertilizer Week, 2000l).

Current Research and Technology

The Iowa State University extension developed a web page featuring a soil temperature map for each county and the statistical probability of temperatures over a period of time. The goal of this project was for producers, agricultural businesses, and fertilizer dealers to apply anhydrous ammonia when soil temperatures are 50° F and trending lower; applying ammonia below this temperature reduces nitrate leaching, which leads to lower nitrogen losses. The web site would use soil temperature data from weather stations around Iowa. The observed soil temperature data would be placed on the World Wide Web and used with air temperature readings to compute soil temperatures for counties without actual observations (Green Markets, 2000e).

Perdue-AgriRecycle introduced a new product called MicroStart60™, the brand name for a fertilizer made from pelletized chicken litter. The company was constructing a $10 million facility in Sussex, DE, that, when completed in early 2001, would be able to process 80,000 t/yr of chicken litter. The company contracted with producers on the Delmarva peninsula to provide the raw material. According to Perdue-AgriRecycle, the nutrient content of the pelletized material is 3% nitrogen, 3% phosphorus, 3% potassium, and 60% organic matter. The company also claimed that the product provides micronutrients such as calcium, copper, iron, magnesium, manganese, sulfur, and zinc, and provides water-insoluble nitrogen that is released slowly over a long period of time, which prevents runoff and resultant nutrient loss (Green Markets, 2000j).

Outlook

According to the USDA, farmers' planting intentions for the eight major field crops (corn, soybeans, wheat, barley, sorghum, oats, cotton, and rice) total 101.8 million hectares in the 2000-2001 crop year, a drop of 1.3% from the last year's planted area. Farmers intend to plant a record 31.0 million hectares of soybeans, 3% more than in 2000 and the 10th straight increase. Corn plantings are expected to be down 4%, wheat plantings are expected to be down by 4%, and projected cotton area, 6.3 million hectares, is the largest since 1995. With adverse weather or significant changes in crop prices, actual plantings could vary from intentions. For example, persistent wet conditions this spring could delay corn plantings and cause an even greater switch from corn to soybeans. Higher fertilizer and fuel costs, reflecting the effect of higher natural gas prices, represent another important factor in the expansion of soybean plantings this year, because corn production uses significantly more nitrogen fertilizer relative to soybeans. According to a cost budget prepared by the University of Illinois extension service, nitrogen costs in corn production will increase by $17 per hectare in the 2000-2001 crop year because of higher nitrogen fertilizer prices (Agricultural Outlook, 2001). Based on these planting projections, U.S. nitrogen consumption is expected to decrease in 2001.

In the longer term, the USDA projects that after a decline in planted acres in the beginning of the decade, corn plantings will increase slightly by 2011, projecting a planted acreage of 32.8

Digitized by Google

million hectares compared with 31.3 million hectares in 2000 (figure 5). Wheat and soybeans follow a similar pattern, with wheat plantings projected to grow to 26.7 million hectares from 25.4 million hectares, and soybean plantings projected to grow to 30.3 million hectares from 29.8 million hectares (U.S. Department of Agriculture, Economic Research Service, February 2001, Agricultural baseline projections, accessed June 12, 2001, at URL http://www.ers.usda.gov/Briefing/baseline). If these projections are correct, U.S. consumption of nitrogen for fertilizer applications is likely to increase.

If natural gas costs remain high, some U.S. production capacity can be expected to close for extended periods or to shut permanently. The New York Mercantile Exchange Henry Hub natural gas futures contract prices are not projected to increase to much more than $4.00 per million British thermal unit through mid-2004, but these costs are generally higher than they had been before the price spike (New York Mercantile Exchange, [undated], Henry Hub natural gas, accessed June 28, 2001, at http://www.nymex.com/markets/quotes.cfm?showAll=on&contract=NG#NG). High natural gas costs in the United States, coupled with projected ammonia and urea capacity increases in South America, could lead to a higher level of imports. Material from this region potentially could be brought into the United States at a significantly lower cost than U.S.-produced material, which could put further pressure on U.S. ammonia and urea producers to close facilities.

PEAT

By Stephen M. Jasinski

Domestic survey data and tables were prepared by Jeff Milanovich, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Peat is a renewable, natural, organic material of botanical origin and of commercial significance. Peatlands are situated predominately in shallow wetland areas of the Northern Hemisphere, where large deposits developed from the gradual decomposition of plant matter under anaerobic conditions.

Peat has widespread use as a plant-growth medium in a variety of horticultural and agricultural applications, where its fibrous structure and porosity promote a unique combination of water-retention and drainage characteristics. Commercial applications include potting soils, lawn and garden soil amendments, and turf maintenance on golf courses. In industry, peat is used primarily as a filtration medium to remove toxic materials from process waste streams, pathogens from sewage effluents, and deleterious materials suspended in municipal storm-drain water. In its dehydrated form, peat is a highly effective absorbent for fuel and oil spills on land and water.

The United States remained a significant producer and consumer of peat for horticultural, agricultural, and industrial purposes. A variety of peat types were extracted and processed from 61 identified operations in 17 of the conterminous United States and by several companies in Alaska. The grades of peat included, in order of importance, reed-sedge, sphagnum moss, hypnum moss, and humus. Florida, Michigan, and Minnesota accounted for 78% of U.S. production. The United States imported one-half of its total domestic requirements, principally from Canada, where deposits of high-quality sphagnum moss are extensive.

U.S. production and sales of peat increased for the fifth consecutive year (table 1). Imports of sphagnum peat from Canada increased by 5%.

Production

Domestic production data for peat were developed from a voluntary survey of operations in the conterminous United States by the U.S. Geological Survey (USGS). Of the 64 operations to which a survey request was sent, 46 responded, representing 75% of total production. Peat production in 2000 was 755,000 metric tons (t), a 3% increase from that of 1999 (table 2).

Geographically, domestic production was dominated by operations in Florida, Michigan, and Minnesota (table 3). Reed-sedge peat accounted for 80.5% of production by weight, followed by hypnum moss, 7.2%; sphagnum moss, 6.4%; and humus, 5.9% (table 4). Peat production in Alaska was estimated to be 30,600 cubic meters in 2000, according to the Alaska Department of Natural Resources (Szumigala and Swainbank, 2001, p. 12), which conducted its own survey of mineral production in the State. Only volume of production was reported.

Consumption

Sales of domestic peat increased by 2% to 847,000 t compared with that of 1999. Packaged products composed 43% of total domestic sales tonnage and commanded premium prices

Peat in the 20th Century

Domestic commercial production of peat was first recorded in 1904, although peat had been used as fuel in New England since the colonial era and was still harvested for local or individual use. By 1908, commercial production of peat had grown to nearly 23,000 metric tons from less than 1,000 tons in 1904. The largest use was as a filler material in chemical fertilizers. Dried, ground peat was added to the fertilizer product to provide nitrogen and improve the consistency and water holding capability. Peat also was used for stable litter and was combined with molasses residue for use as stock feed. Early in the century, considerable interest was given to using peat as a fuel source, especially after a strike by anthracite coal miners in 1902 to 1903. Some small peat powerplants did operate intermittently throughout the century, but abundant U.S. resources of wood, coal, oil, and natural gas made it difficult for peat to be a cost-effective fuel source. Peat was harvested by draining the bog, plowing the peat, and forming it into windrows to air dry. When the peat had dried to about 50% moisture, it was transported to a mechanical dryer, which lowered the moisture content to 10%. It was then screened to remove waste matter and sold. At the end of the century, peat was harvested by the same basic methods; such specialized machinery as the pneumatic harvester, however, greatly improved efficiency. From about 1930 to 2000, peat had been used primarily as a soil conditioner in such applications as golf course improvement, potting soil mixes, general nursery use, and vegetable growing.

In 2000, the United States produced 755,000 tons of peat and imported 786,000 tons, mostly from Canada. Consumption grew steadily in the 1990s as horticultural business benefited from demand generated by new construction of houses, commercial buildings, golf courses, and recreational facilities. The total sales value of domestic peat in 2000 was $22.7 million, and imports were valued at $157 million. World production was estimated to have been about 27 million metric tons, with more than one-half used as fuel.

Digitized by Google

for all grades except humus. Apparent consumption decreased by 5% from that of 1999. General soil improvement and potting soil mixes were the two largest usage categories, accounting for 82% of domestic sales. Other significant uses included mixed fertilizers, nursery applications, golf course applications, and seed inoculants. Imports of sphagnum moss from Canada accounted for nearly 50% of U.S. consumption. Canadian peat was sold in bulk for blending in soil mixes and packaged for horticultural use.

Scotts Co. purchased the worldwide distribution rights for horticultural peat and peat products manufactured by Bord na Móna plc of Ireland. Scotts will market the products under the Shamrock® brand, which it had acquired from Bord na Móna in 1998 for distribution in Ireland and the United Kingdom. Currently [2000], the products are marketed to professional growers but will be expanded to the consumer market in the future (Scotts Co., 2000).

Stocks

U.S. yearend stocks of peat increased by 3% to 279,000 t (table 4). Reed-sedge peat accounted for 92% of total stocks, followed by humus, sphagnum moss, and hypnum moss.

Prices

The total reported free on board (f.o.b.) value for domestic peat sold in the United States was $22.7 million according to the annual survey of domestic peat producers conducted by the USGS. The average unit value increased to $26.85 per metric ton compared with $26.48 per ton in 1999. Packaged peat sold for a higher value for all grades except humus. On a unit-value basis, packaged sphagnum moss was valued at $68.42 per ton, f.o.b. plant; hypnum moss, $52.47 per ton; reed-sedge, $24.33; and humus, $17.86 per ton (table 7).

Foreign Trade

Imports of peat increased by 3% to 786,000 t in 2000 (table 8). The total customs import value was $157 million or $199.65 per ton. Imports of sphagnum moss from Canada increased to 783,000 t, which represented 64% of total Canadian production. The United States exported 37,000 t of peat.

World Review

World production decreased to 27.4 million metric tons (Mt) in 2000 compared with 29.5 Mt in 1999. According to information available to the USGS, 22 countries reported peat production (table 9). Production was dominated, in order of importance, by Finland, Ireland, Germany, Belarus, Russia, and Canada. Other significant producing counties included Sweden, Estonia, the United States, and Latvia. Peat is an important source of energy in Ireland, Scandinavia, and the former Soviet Union (FSU). In 2000, at least 14.7 Mt of reported world production was for fuel use. Most of the unspecified uses were believed to have been for horticultural use; however, information was not available to make an accurate estimate.

Estimated production from countries of the FSU accounted for a significant portion of global peat production, although output from the region has decreased since 1990. Political restructuring, the reduced use of peat as a fuel, and unfavorable economic trends were all believed to have been major factors responsible for the drop in production.

In Canada, production of sphagnum moss decreased by 7% to 1.23 Mt (table 9). New Brunswick, Quebec, and Alberta were the major producing provinces, in order of importance (Natural Resources Canada, 2000, Preliminary estimate of the mineral production of Canada, by province—2000, accessed July 27, 2001, at URL http://www.nrcan.gc.ca/mms/efab/mmsd/production/2000.pdf). Exports to the United States increased to 783,000 t.

Outlook

The outlook for horticulture and associated business is bright because global demand for plants, flowers, ornamental trees, natural turf, and outdoor recreational activities continues to grow at a substantial rate. The outlook for the domestic peat industry, therefore, will likely be governed by several variables, including future wetlands environmental regulations, the ability to permit new bogs, growth and competition from recycled yard wastes and other natural organic materials, Canadian competition, and the degree of market penetration by flowers and ornamental plants from abroad.

PERLITE

By Wallace P. Bolen

Domestic survey data and tables were prepared by Virginia C. Harper, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

In 2000, whereas imports of processed perlite increased compared with 1999, the amount of domestic processed perlite sold and used decreased. The amount of perlite expanded, sold, and used by domestic expanders also decreased in 2000. Increased demand for horticultural aggregates, loose fill insulation, and miscellaneous uses was more than offset by decreases in demand for construction products, fillers, laundries, low temperature insulation, and plaster aggregate.

Production

According to the U.S. Geological Survey (USGS), the amount of U.S. processed perlite sold or used decreased by about 5.5% to 672,000 metric tons (t) compared with that of 1999. The value of processed perlite sold or used decreased by 4.4% to $22.7 million compared with that of 1999. The amount of expanded perlite sold or used by domestic producers decreased 1.9% to 715,000 t, and the associated value remained about the same compared with that of 1999 (table 1).

Domestic production data for perlite are derived by the USGS from two voluntary annual surveys—one for domestic mine operations (processed perlite) and one for expanding plants. All the processed perlite included in table 1 was produced by 11 mines operated by 9 companies, and 9 of the 11 operations responded to the USGS survey. The perlite was mined in Arizona, California, Idaho, Nevada, New Mexico, Oregon, and Utah; New Mexico operations accounted for the vast majority of the total tonnage mined. Ore producers, in alphabetical order by State, were Harborlite Corp. in Arizona and New Mexico; American Perlite Co. in California; Idaho Minerals LLC in Idaho; Wilkins Mining and Trucking, Inc. and Eagle-Picher Minerals, Inc., in Nevada; Cornerstone Industrial Minerals Corp. in Oregon; Dicaperl Corp. and USG Corp. in New Mexico; and Basin Perlite Co. in Utah. Of the 63 expanding operations canvassed, 62 were active. Of those, 49 operations (78%) responded, reporting about 90% of the total expanded perlite sold or used (table 1). The top seven producers of expanded perlite, each with production of more than 30,000 metric tons per year, accounted for nearly 85% of expanded perlite sold or used in the United States in 2000. The remaining 15% was sold or used by 26 companies.

Consumption

Domestic apparent consumption is defined as U.S. processed perlite sold and used plus imports minus exports. In 2000, domestic apparent consumption of processed perlite was 809,000 t, a slight increase compared with that of 1999. Consumption of expanded perlite for construction-related uses, which was the major market for expanded material, decreased by 5.9% to 494,000 t. Construction uses of expanded perlite, which consisted of concrete aggregate, formed products,

Perlite in the 20th Century

Expanded perlite was not available in 1900, because the effect of heat treatment to expand perlite was not discovered until 1928, and controlled experiments using perlite from near Superior, AZ, were not undertaken until 1940. Although not extensively used until 1945, expanded perlite was being used as a lightweight aggregate, as loose fill for insulation, and as chicken litter, while the finest grained perlite was being used in cleansers. The building boom after World War II helped perlite gain market share in competition with expanded slag, clay, vermiculite, and other lightweight materials. At least nine companies were actively experimenting on perlite expansion, and several hundred metric tons had been produced commercially in Arizona, California, and Nevada. After several years of pilot-plant development, the perlite industry started commercial production in 1946, when the output reached 3,820 tons. Five companies reported production, mostly from the Superior area of Arizona and one from near Beatty, NV. All of the material sold in 1946 was used by the construction industry as thermal insulation and lightweight aggregate. The average price of processed perlite was about $41 per ton in 1946. By 1948, it had dropped to about $21.50 per ton. In 1948, the first statistics for expanded perlite were available: 36,700 tons valued at $1.98 million, or about $54 per ton, was produced.

By 2000, production of processed perlite in the United States was 672,000 tons and expanded perlite consumption was 715,000 tons. Imports of perlite were about 180,000 tons. Domestic production was mainly from mines in New Mexico with much smaller amounts coming from mines in Arizona, California, Idaho, Nevada, Oregon, and Utah. Most of the expanded perlite was produced east of the Mississippi River. Construction related uses accounted for most expanded perlite consumption, but instead of being used as loose insulation or aggregate, most of the expanded perlite was used in formed products such as ceiling tiles.

Digitized by Google

masonry- and cavity-fill insulation, and plaster aggregate accounted for about 69% of total domestic sales in 2000. Expanded perlite consumption increased for horticultural aggregate, masonry- and cavity- fill insulation, and miscellaneous uses. Consumption decreased for all other uses (table 3). Perlite was expanded, usually for local consumption, in 31 States. The leading States in production of expanded perlite sold or used were, in descending order, Mississippi, Georgia, Illinois, Pennsylvania, Alabama, Minnesota, and Virginia (table 2).

Prices

Processed perlite sold at an average value of $34.39 per metric ton, which was up 2.8% compared with that of 1999. Perlite consumed by expanding plants operated by the mining companies was valued at $30.69 per ton, which was a decrease of 7.4% compared with that of 1999. The average price for all perlite sold or used by mining companies was $33.78 per ton, which was up 1.1% compared with that of 1999. The average price of expanded perlite was $207 per ton, up from $203 in 1999; the range in reported prices was, however, wide—from less than $100 to more than $1,000 per ton.

The average prices by use per ton of expanded perlite, in descending order, were low-temperature insulation, $410; fillers, $402; masonry- and cavity-fill insulation, $401; filter aid, $322; concrete aggregate and horticultural aggregate (tied), $318; plaster aggregate, $300; laundries, $277; and formed products, $144 (table 3).

Foreign Trade

Exports of processed and expanded perlite, primarily to Canada, were estimated to be 43,000 t, which was a 9% decrease from that of 1999. Imports of processed perlite, almost exclusively from Greece, increased by about 25% to about 180,000 t. Import and export data were derived from U.S. Census Bureau data, the Journal of Commerce's Port Import and Export Reporting Service, and importers and exporters.

World Review

The United States was estimated to be the largest producer and consumer of crude and expanded perlite. Other leading producers of processed crude perlite were, in descending order, Greece, Japan, Hungary, and Turkey (table 4). In 2000, 13 countries produced 1.91 million metric tons of perlite. Owing to a lack of reliable figures, however, this total does not include several producing countries, such as China, which was probably the largest or second largest producer in the world.

Outlook

Total consumption of expanded perlite and processed perlite in the United States is expected to increase slightly in 2001. Growth in imports of processed perlite is expected to slow the growth of domestic processed perlite sales. The growth in Canadian horticultural perlite demand may, however, result in increased exports of domestic processed perlite. The new mines in the Western United States and continued growth in imports are expected to restrain price increases for many grades of processed perlite.

PHOSPHATE ROCK

By Stephen M. Jasinski

Domestic survey data and tables were prepared by Christopher H. Lindsay, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Phosphorus is an essential element for plant and animal nutrition. Phosphorus is consumed primarily as a principal component of nitrogen-phosphorus-potassium (NPK) fertilizers that are used to enhance the growth of food crops throughout the world. Phosphate rock minerals are the only significant global resources of phosphorus.

The United States is the world's leading producer and consumer of phosphate rock and phosphate fertilizers. Domestic production decreased for the second consecutive year owing to the closure of two mines and lower production rates at several others. Mines in Florida and North Carolina accounted for 86% of domestic marketable production, with the remainder produced in Idaho and Utah. More than 90% of the phosphate rock mined was used to produce chemical fertilizers and animal feed supplements; the remainder was used to produce elemental phosphorus (P_4) and other industrial phosphates. Two companies in Idaho produced P_4 for downstream industrial compounds.

Domestic consumption and sales of marketable phosphate rock decreased by 10% from that of 1999. Manufacturers of phosphate fertilizers continued to be affected by weak export sales, primarily to China and India, which have been the major destinations for U.S. fertilizer exports for the past decade. In response to market conditions, several phosphoric acid plants were closed temporarily during the year, resulting in a drop in consumption of phosphate rock. Imports of phosphate rock were down by 11% after reaching a record high in 1999. The U.S. Census Bureau reported that wet process phosphoric acid (WPPA) production was 11.4 million metric tons (Mt) as available phosphorus pentoxide (P_2O_5) compared with 12.2 Mt in 1999 (U.S. Census Bureau, 2001). U.S. producers accounted for nearly 40% of world trade in converted phosphate products (Demetriou, 2001, p. 7). The major fertilizer products were diammonium phosphate (DAP), monoammonium phosphate (MAP), triple superphosphate (TSP), and WPPA.

Legislation and Government Programs

The U.S. Drug Enforcement Administration (DEA) proposed classifying red phosphorus, yellow phosphorus, and hypophosphorous acid as controlled substances or List I chemicals because they have been identified as being important chemicals for the illicit manufacturing of methamphetamine. Handlers of List I chemicals are subject to the Controlled Substances Act regulatory controls including registration, recordkeeping, reporting, and import/export requirements. The DEA determined that these controls are necessary to prevent the diversion of these chemicals to drug laboratories. The agency did not propose a threshold limit for reporting because there are few legitimate uses for the compounds, and only small quantities of the substances are required to manufacture methamphetamine. Industrial uses of red phosphorus include pyrotechnics, matches, incendiary shells, tracer bullets, and other phosphorus compounds. Red phosphorus and

Phosphate Rock in the 20th Century

In 1900, the United States was the largest producer of phosphate rock in the world, accounting for 48% of world production of 3.15 million metric tons. By that time, Florida had become the dominant producing State surpassing South Carolina, where phosphate rock was first discovered and mined in the United States in 1867. At this time, mining had begun shifting from river dredging to exploitation of hard rock and land-pebble deposits. Mining was accomplished by horse- and mule-drawn scrapers, pick and shovel, and in a few instances, steam shovels. By 1904, manual methods had been replaced by electric shovels to remove the overburden, and hydraulic pumps were used to move matrix to the washer plant. The implementation of the dragline in 1920 greatly improved efficiency by reducing labor and increasing the quantity of ore mined. In 1928, the flotation process was patented enabling companies to recover up to 95% of the phosphate that was previously discarded. Phosphate rock mining began in the Western United States in 1907 and in North Carolina in 1966. Phosphate rock production capacity doubled from 1960 to 1970 in response to increased demand for fertilizer and the shift to multinutrient, high-analysis fertilizers. Throughout the 20th century, fertilizer production was the major use of phosphate rock. Elemental phosphorus production and industrial applications never achieved more than 10% of total domestic usage.

In 2000, the United States remained the largest producer of phosphate rock in the world, accounting for nearly 29% of total world production of 133 million tons, and was the largest consumer of phosphate rock and largest exporter of phosphate fertilizers. Florida remained the largest producing State, followed by North Carolina, Idaho, and Utah. The United States was a major world supplier of phosphate rock until the early 1990s when producers shifted emphasis to exporting higher value fertilizer materials.

Digitized by Google

hypophosphorous acid are derivatives of P_4 and the DEA estimates that only 2% of the P_4 produced domestically is converted into a form that will be subject to the regulation (U.S. Department of Justice, 2000).

Production

Domestic phosphate rock production data were developed by the U.S. Geological Survey from monthly and semiannual voluntary surveys of producers of phosphate rock. All companies responded to the canvass.

Phosphate rock production decreased for the second consecutive year, reaching its lowest point since 1993 (tables 1, 3). The phosphate industry was affected by a significant drop in export sales of DAP, the largest volume fertilizer product, and of phosphoric acid. Marketable output from Florida and North Carolina was down by 4%, owing to the closure of one mine in late 1999 and another in August 2000. Overall, production rates at the other mines were nearly the same as in 1999; consumption, however, dropped by 10%, and therefore stocks increased substantially. In Idaho and Utah, production declined by 10% owing to the combined effects of a temporary closure of one mine, stock depletion, and seasonal demand fluctuation. U.S. mine production was at 86% of rated annual capacity (table 13).

Southern States.—In Florida, phosphate rock was mined and processed by five companies: Agrifos, L.L.C.; Cargill Fertilizer, Inc.; CF Industries, Inc.; IMC Phosphates MP, Inc.; and PCS Phosphate Co., Inc. Their mines and plants were located in Hamilton, Hardee, Hillsborough, and Polk Counties (table 2). The Nu-Gulf Industries, Inc., Wingate Creek Mine in Manatee County was closed for the entire year. U.S. Agri-Chemicals Corp. and Farmland Hydro L.P., a joint venture between Farmland Industries, Inc., and Norsk Hydro ASA, operated WPPA and ammonium phosphate plants at Fort Meade and Green Bay, respectively, using phosphate rock purchased from other companies in Florida.

In December, Farmland-Hydro L.P. submitted a permit application to open a 6,114-hectare (ha) phosphate rock mine in Hardee County. According to the company, planned production will be 2.7 million metric tons per year (Mt/yr) for 30 years. A beneficiation plant will be built onsite, and the phosphate rock will be sent by rail to the Fort Meade WPPA facility in Polk County. Under Florida's ecosystem management team permitting process, the consolidated development application (CDA) is filed simultaneously with all appropriate Federal, State, and local agencies after the company conducts meetings with all interested parties. The application requires the demonstration of a net benefit to the environment in the form of the reclamation plan that restores a greater area of land than is disturbed. The firm anticipates receiving the permit by the end of 2001 (Green Markets, 2001b).

In May, IMC Phosphates filed a CDA for its proposed Ona Mine in Hardee County. The mine would encompass 8,335 ha, of which 24% of the area would not be disturbed. Total minable reserves are estimated to be 150 Mt. According to IMC, during the first 8 years of operation, it plans to mine 2.72 Mt/yr, and for the balance of the 24-year life of the facility, it will mine 5.45 Mt/yr. For each hectare of wetlands disturbed, it will create an average of 1.6 ha. Approval was anticipated by the end of 2001. IMC expected to submit a CDA for the proposed Pine Level Mine in DeSoto County in 2001 or 2002 (Green Markets, 2000d).

Agrifos closed its Nichols Mine in August in response to economic conditions, according to the company. Prior to the closure, production was limited because of excess water in the mine. Nichols was one of the smallest phosphate rock mines in Florida, with a production capacity of 1.1 Mt/yr. No decision had been made on whether the mine and its reserves would be sold. The Agrifos Fertilizer, LLC, plant in Pasadena, TX, would not be affected by the closure; it would rely exclusively on imported rock. Duke Energy Corp. acquired a financial interest in Agrifos, and Duke's wholly owned subsidiary, Duke Energy Merchants, L.L.C., will assume product sales and raw material purchasing responsibilities for the Pasadena facility (Green Markets, 2000e).

Mulberry Corp., the parent company of Mulberry Phosphates, Inc., Piney Point Phosphates, Inc., and Nu-Gulf Industries, ceased operations at all facilities in 1999, all of which remained closed in 2000. In December, the Florida Department of Environmental Protection (FDEP) sought to suspend the company's operating permits for its two processed phosphate plants because of failure to comply with orders to correct groundwater contamination (Green Markets, 2000b). In early 2001, Mulberry filed for chapter 11 bankruptcy protection and abandoned its facilities. The FDEP was then forced to maintain the Mulberry and Piney Point plants after Mulberry could not pay its electric bill. Although the plants had been closed for more than a year, electric pumps circulated water continuously through the phosphogypsum stacks. If the power were turned off, the acidic water could overflow into nearby waterways (Green Markets, 2001c).

Six concentrated phosphate plants were located along the Gulf of Mexico. IMC Phosphates operated a phosphoric acid plant at Uncle Sam, LA, using phosphate rock from the firm's mines in Florida and a DAP/MAP granulation facility at Faustina, LA. Both plants were closed for several months between January and October and then closed indefinitely in November owing to market conditions. The company's Taft, LA, DAP granulation facility and the Faustina phosphoric acid plant were closed for the entire year (IMC Global Inc., 2000, p. 3). The PCS Nitrogen Inc. plant in Geismar, LA, and Mississippi Phosphates Corp. plant in Pascagoula, MS, both used phosphate rock imported from Morocco. The Agrifos plant in Pasadena, TX, used both phosphate from the company's Nichols Mine in Florida and imports from Morocco.

Idaho and Utah.—In Idaho, four companies conducted open pit mining in Caribou County (table 2). Astaris L.L.C. operated the Dry Valley Mine on Federal and private leases, to provide feedstock for P_4 production at its Pocatello plant. Monsanto Co. operated the Enoch Valley Mine, which supplied its P_4 plant in Soda Springs. Agrium Inc. produced phosphate rock from the Rasmussen Ridge Mine to feed its Conda WPPA and DAP plants. J.R. Simplot Co. operated the Smoky Canyon Mine,

Digitized by Google

which supplied its WPPA plant in Pocatello, by a 138-kilometer (km) slurry pipeline.

In October, Agrium was forced to close its phosphoric acid plant after a wall of a digester tank collapsed, which resulted in the spill of phosphoric acid and rock slurry. The plant was reopened in December at 80% capacity. The tank was scheduled for replacement in 2001 as part of the Agrium-Astaris joint-venture project to produce purified phosphoric acid, which will increase annual WPPA production capacity at the plant to 375,000 metric tons per year (t/yr) from 280,000 t/yr P_2O_5 (Agrium Inc., 2001, p. 23).

Astaris began implementation of an emission reduction program and site modifications to its Pocatello facility that were mandated by the U.S. Environmental Protection Agency in 1999 for violations of the clean air and water regulations (Green Markets, 2000c). In September, Astaris announced plans to reduce P_4 production by closing two of the four electric furnaces at its Pocatello, ID, plant in 2002. The company cited market conditions and the construction of a new purified phosphoric acid plant, which would be operated by Agrium and Astaris, as reasons for the closure (Green Markets, 2000a). In April 2001, Astaris accelerated its closure plan and reduced operations to one furnace in response to the rising cost of electricity (Green Markets, 2001a).

In Utah, SF Phosphates Ltd., Co., a joint venture between Simplot and Farmland Industries, Inc., operated a major mining and phosphate rock beneficiation facility near Vernal. The beneficiated phosphate rock was transported by slurry pipeline 155 km to the company's phosphate fertilizer production plant at Rock Springs, WY.

Universal Chemical Corp. continued in its efforts to obtain financing to open a phosphate rock conversion facility in eastern Utah. The company plans to use phosphate rock from the Ashley Valley Phosphate Co. deposit that is located near Vernal. Universal plans to process the phosphate ore with a method that was developed in Europe but never used in North America. Unlike conventional phosphoric acid production, which uses sulfuric acid to digest the rock, the rock would be treated with a weak hydrochloric acid solution onsite, which readily separates the silica, clay, and other impurities from the phosphate. The resulting phosphate-calcium solution would be transported by pipeline 71 km to the plant and the remaining inert material would be used for mine reclamation. The phosphate solution would be used to produce dicalcium and monocalcium phosphate for animal feed supplements and phosphoric acid. The byproduct calcium chloride could be reacted with sulfuric acid to manufacture food-grade gypsum. The State of Utah received a Federal grant of $870,000 to study the extension of a railroad line from the site of the proposed plant in Bonanza to connect with an existing rail line at Rifle, CO. The State has been working for more than 2 years on an economic development proposal that includes the 1,370-ha phosphate mine, a phosphate processing facility, a gypsum wallboard plant, a fertilizer plant, administration offices, and the 82-km short-line railroad. As of December 31, the company was in the process of obtaining financing for the project (Green Markets, 2000f).

Consumption

In 2000, apparent consumption was at its lowest level since 1993, and reported phosphate rock sold or used was at the lowest point since 1971 (table 4). Both decreased by 10% from that of 1999 owing to a drop in phosphoric acid production (U.S. Census Bureau, 2001). The weak market conditions that began in 1999 continued throughout 2000, with domestic producers exporting less to China and India because of increased competition, lower demand, new plants opening in the region, and high world inventories. Several fertilizer manufacturers in the Southern States temporarily closed production facilities in response to the significant decrease in DAP export sales. The major fertilizer producers in the South rely on exports for the bulk of their business, because the domestic market is mature and normally fluctuates very little from year to year. Domestic consumption of P_2O_5 contained in fertilizer increased slightly for the crop year ending June 30 (Terry and Kirby, 2001, p. 6).

Phosphate rock used in the Western United States fell slightly because of the temporary closure of the Agrium plant, which resulted in a concurrent drop in rock production and seasonal fertilizer demand fluctuations. Western fertilizer manufacturers only sold their products domestically and were not affected by the world market situation. The only two P_4 plants in the Western Hemisphere are located in Idaho. Approximately 65% of P_4 was consumed to manufacture thermal phosphoric acid, which was used directly in detergents, food additives, water- and metal-treatment chemicals, and soft drinks, and as a raw material to make calcium, potassium, and sodium phosphates. The other 35% of P_4 was used directly to manufacture phosphorus trichloride, pentasulfide, and other compounds that were used in herbicides, insecticides, flame-retardants, lubrication greases, and plasticizers. Production of thermal phosphoric acid was 283,000 metric tons (t) of P_2O_5 compared with 259,000 t in 1999 (U.S. Census Bureau, 2001). Exports of P_4 fell to 3,440 t from 5,740 t in 1999 (table 11).

Purified wet-process phosphoric acid (PWA), which is less costly to produce than thermal acid, had attained a greater market share than thermal acid as a raw material for industrial phosphorus derivatives (Hume and others, 2000). PWA can be used to produce most phosphorus compounds except phosphorus pentasulfide and phosphorus trichloride, which is used to make herbicides, pesticides, and flame-retardants. U.S. P_4 production capacity was expected to drop to about 150,000 t/yr in 2001 from 236,000 t/yr to with the closure of three of the four furnaces at the Astaris plant in Pocatello, ID. Astaris will then begin producing PWA at a new 80,000 t/yr facility it will operate with Agrium at Soda Springs, ID (Green Markets, 2000a).

Stocks

U.S. stocks of phosphate rock ended the year 18% higher than in 1999 owing to the temporary closure of several phosphoric acid plants in Florida and Louisiana. Mine production continued on a regular schedule in anticipation of building stock

Digitized by Google

when the plants eventually reopen. By region, stocks increased by 27% in Florida and North Carolina and dropped by 10% in Idaho and Utah (table 3).

Transportation

In Florida, beneficiated phosphate rock was moved by rail and truck to phosphoric acid plants within the State. Phosphate rock, phosphate acid, fertilizers, and animal feed supplements were sent by rail or truck to the port of Tampa and then were shipped for domestic use or export. More than 22 Mt/yr of phosphate-related materials move through the port of Tampa, representing nearly 50% of total tonnage handled at the port (Tampa Port Authority, 2000, Bulk cargo, accessed April 3, 2001, at URL http://www.tampaport.com/bulkcargo.htm).

Phosphate fertilizers produced by companies along the Gulf of Mexico were transported primarily by barge on the Mississippi River and its tributaries, by rail, and by truck for domestic consumption. Exported products were shipped directly from major ports along the Gulf of Mexico. PCS Phosphates operated a port facility at Morehead City, NC, for export and import. Phosphates produced at its Florida facilities were sent by rail to Morehead City. In the West, phosphate ore was sent from the mine via truck, rail, and slurry pipeline to production facilities.

Prices

The average price for domestic phosphate rock decreased by 21% in 2000 (table 5).

Foreign Trade

Imports of phosphate rock were estimated to be 1.93 Mt, an 11% decrease from that of 1999. Reported imports from the U.S. Census Bureau were 665,000 t because some data were suppressed (table 12). More than 99% of all imported phosphate rock was from Morocco and primarily used by three companies: Agrifos, Mississippi Phosphates, and PCS Nitrogen.

Phosphate rock exports increased by 10% to 299,000 t (table 6). Domestic exports of DAP, the major phosphate fertilizer product, dropped by 27% compared with 1999 because of reduced purchases by China and India. Exports of DAP to India were down by 85% from the previous year owing to large inventories, government subsidy programs that encourage purchasing from Indian companies, and lower demand. The Oswal Chemicals and Fertilizers Ltd. 1.5-Mt/yr DAP plant began production early in the year; however, it never achieved full operating capacity because of phosphate rock supply problems (Fertilizer International, 2000c). The IndoGulf Corp. 400,000-t/yr DAP plant was commissioned in September and, unlike Owsal, the facility used imported WPPA (Fertilizer International, 2000b). Neither plant had a significant impact on trade. China imported 11% less DAP from the United States because of lower demand, high inventory, and increased internal production. Phosphoric acid and concentrated superphosphate exports also decreased, while MAP exports increased by 28% (tables 7-10). Overall, the United States accounted for 40% of total world trade in processed phosphates. By product, DAP accounted for 61% of the total world trade, followed by MAP with 25% and TSP with 14% (Demetriou, 2001, p. 7).

World Review

World production was estimated to have decreased to 133 Mt from 137 Mt in 1999 (table 14). The United States, Morocco, China, and Russia accounted for 65% of total production, by order of output. In addition to lower production, worldwide shipments of phosphate rock decreased for both export and internal consumption, while stocks increased (Demetriou, 2001, p. 6). The closure of two phosphoric acid plants in the Netherlands and the opening of a phosphate rock mine in Canada reduced trade in phosphate rock in Europe and North America. In Asia, such traditional suppliers as Jordan, Morocco, and Togo faced increased competition from China. World consumption of phosphate rock, which closely mirrors production, was estimated to have fallen slightly. Consumption of P_2O_5 for fertilizer increased slightly (Prud'homme and Soh, 2000). New fertilizer plants in Australia and India, which began operation in late 1999, had difficulties achieving full operating capacity but apparently corrected problems by the end of the year.

Australia.—WMC Fertilizers Pty. Ltd. started production at its Queensland Mine, which supplied its nearby fertilizer plant complex. The mine has a rated capacity of 2.2 Mt/yr and demonstrated reserves of 100 Mt. The mine was expected to be operating at full capacity in 2001, after two major problems were corrected with the fertilizer plant. Early in the year, the phosphoric acid plant experienced problems with the agitator blades in two reactors, and then the entire ammonia plant was closed for several extended periods for retooling. By October, the facility was operating at 60% of annual production capacity (WMC Ltd., 2001).

China. — Spur Ventures, Inc., released the results of a feasibility study of the Yichang phosphate project in central China. The project consists of five phosphate rock deposits containing 579 Mt of reserves averaging 21.2% P_2O_5. The company proposes to vertically integrate mining and fertilizer production to manufacture high-analysis fertilizers. Anticipated mine production will be 1.25 Mt/yr of phosphate concentrate. A 126-km long, 22-centimeter diameter pipeline was proposed to be built to transport the concentrate to the chemical plant near the Yangtze River. The fertilizer plant would produce either NPK compounds or DAP. Initial capacity would be 480,000 t/yr DAP and 529,000 t/yr NPK. Total estimated cost of the project was $371 million (He, 2000).

The Phosphate Chemicals Export Association, Inc. (PhosChem) signed a 2-year extension to its existing DAP supply contract with China National Chemicals Import and Export Corp. (Sinochem). The new pact would run through December 31, 2002, and under the terms of the agreement, Sinochem would purchase unspecified monthly shipments with an option to purchase additional tonnage (Phosphate Chemical

Digitized by Google

Export Association, Inc., 2000).

Cargill was planning to assist the Yunnan Phosphate Fertilizer Factory in upgrading its phosphoric acid plant and adding a DAP granulation facility with a capacity of 600,000 t/yr. Each company would contribute $15 million to the project. Yunnan Province had about 20% of the country's phosphate rock reserves, but only about 10% to 15% was considered suitable for WPPA production (Fertilizer Markets, 2000a).

The U.S. Trade Representative negotiated a United States-China fertilizer trade agreement in April that would become effective with China's accession into the World Trade Organization (WTO). The agreement established a tariff rate quota for certain fertilizers and expanded the opportunities for direct sales and distribution by foreign companies in China. The agreement set a quantity subject to a quota tariff of 4% and any tonnage above the amount would be subject to a 50% tariff. The DAP quota would start with a tonnage of 5.5 Mt and increase gradually to 6.9 Mt over 6 years. The Chinese Government would have to set the quota by January 1 of each year and could not revise it during the year.

The other provision, which would take effect after 5 years, would allow free trade in fertilizers within China by foreign-owned companies. Prior to the agreement, companies were required to enter into joint-venture agreements with Chinese companies and could not be the majority partner (The Fertilizer Institute, 2000).

Guinea-Bissau.—The Federal Government formalized mining leases on the Champion Resources, Inc., Farim phosphate rock deposit. The leases would be valid for 25 years and automatically renewable for another 25 years. Champion released the results of the final mine plan study. The report indicated recoverable reserves of 166.2 Mt of phosphate ore grading 29.8% P_2O_5, a 58% increase in tonnage from initial tests conducted in 1999. The initial 15-year mine plan anticipated a production rate of 2.47 Mt/yr of 31% P_2O_5 concentrate, which would be upgraded to 32% to 34% P_2O_5. Champion must still finalize financing agreements for the project (Fertilizer International, 2000a).

Jordan.—Norsk Hydro decided against entering into a joint venture with Jordan Phosphate Mines Co. (JPMC) to build a 440,000-t/yr phosphoric acid plant near the JPMC Eshidiya Mine and two 627,000-t/yr DAP/NPK plants at Aqaba. Hydro cited that it had given higher priory to other projects; the rise in worldwide P_2O_5 capacity, low DAP prices, and Indian subsidy programs that limit imports, however, were believed to have influenced the decision. The project was to be part of the JPMC long-term plan to gradually increase mine production at Eshidiya while decreasing production at its other two mines. Financing for the construction of a rail line from Eshidiya to Aqaba was being reevaluated because it would have been primarily for this project. JPMC had not announced whether another partner would be sought or if it would attempt to finance the project independently (Fertilizer Markets, 2000b).

Saudi Arabia.—Saudi Arabian Mining Co. approved development of the Al Jalamid phosphate project in the northwestern part of the country. The project would consist of a mine and DAP plant, focusing on the export market. The Al Jalamid deposit had proven reserves of 216 Mt, with an average grade of 32.5% P_2O_5. Based on an average mine output of 4.3 Mt/yr, the deposit could be mined for more than 50 years. The proposed DAP plant would have an annual capacity of 2 to 4 Mt/yr, although initial capacity would be around 1 Mt/yr and would be adjusted to market conditions. The mine was located about 1,100 km from the port of Al Jubail and no transportation links existed between the mine and port. A rail line had been considered and other options were being evaluated. A five-part detailed mining study started in midyear and was expected to be completed in mid-2001. Construction would not begin until the third quarter of 2001 at the earliest (Fertilizer International, 2001).

Outlook

The short-term outlook for the domestic phosphate industry will depend upon how quickly exports of processed phosphates, primarily DAP, can return to the levels achieved prior to 2000. Phosphate rock production and consumption in the Florida-North Carolina region will likely be lower in 2001 because of the high inventories accumulated in 1999 and 2000 and the indefinite closure of two mines and several fertilizer plants during the same period. Output and demand in Idaho and Utah is expected to remain steady. The opening of a new PWA plant will offset the reduction in P_4 production capacity.

World production of phosphate rock, which has been on a downward trend for the past 2 years owing to reduced demand by fertilizer manufacturers, will begin to increase at about the same rate as fertilizer consumption. World demand for phosphate fertilizer is projected to grow at a rate of 2.3% per year over the next decade according to industry analysts. The ever-increasing world population and the need for adequate food supplies ensure the long-term growth for the industry. The largest demand growth will occur in China, India, and developing countries in Asia and Latin America. Nearly two-thirds of U.S. DAP export sales in recent years have been to China and India. Changes in world production and trade patterns, however, especially related to India, have affected U.S. producers significantly. The drop in exports in 2000 was attributed more to supply and demand issues than the effect of new DAP/MAP plants that have opened in Australia and India. The full impact of the new plants on world trade is expected to occur in late 2001 when they should be operating at near rated capacity. Future trade to India also will depend upon government subsidy programs that limit imports.

China has become the most important export market for domestic fertilizers. China has abundant phosphate rock reserves and is a major exporter, but it lacks fertilizer production capacity. Several phosphate fertilizer production facilities are set to open within 5 years, but imports will still be necessary for some time. As demonstrated in 2000, Chinese demand has been very inconsistent and has been affected by low grain prices, use of cheaper NPK compounds, an effort to limit imports, and high inventories. U.S. exports to China and India are expected to be less in 2001, but the potential for sales to China would improve if the country were accepted as a member

Digitized by Google

of the WTO. Shipments of fertilizer to Latin American have increased but will not fully replace lost sales to India and China.

PLATINUM-GROUP METALS

By Henry E. Hilliard

Domestic survey data and tables were prepared by Mahbood Mahdavi, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

In 2000, the average price of palladium, platinum, rhodium, and ruthenium increased by 90%, 45%, 120%, and 219%, respectively. The price increases for platinum and rhodium can be attributed to increased demand, mainly from the automobile sector. Palladium prices, for the third consecutive year, were influenced by unreliable imports from Russia. Russia accounted for 51% of U.S. palladium supply and 3% of U.S. platinum supply in 2000. Prices for the relatively unknown ruthenium increased sharply to to an average $129.76 per troy ounce in 2000 from $40.70 per ounce in 1999. Ruthenium prices were driven by increased demand from the electronics sector and reports of the development of new ruthenium-based superalloys for use in aerospace applications.

Higher prices were followed by an increase in the pace of exploration for PGM, and a growing number of joint ventures were signed in recognition of the strong fundamentals for these metals. Decreases in the price of PGM in the first part of 2000 did little to dampen enthusiasm for further exploration because of expected increases in demand from the automobile industry, jewelry manufacturing, and other industrial applications as well as limited supplies of the metals from Russia.

The automobile industry continued to be the major consumer of PGM. In 2000, autocatalysts accounted for approximately 98% of rhodium demand, 66% of palladium demand, and 41% of platinum demand. Despite the overall increase in vehicle sales in 2000, demand for palladium by auto manufacturers declined, as automakers and electronic component makers made concerted efforts to reduce the palladium content of their products. U.S. demand for platinum in jewelry manufacture, on the other hand, continued to grow and has become one of platinum's largest applications. Demand for platinum in the automobile industry increased in Europe due to higher loadings on catalysts in diesel automobiles. Diesels have been gaining substantial market share in Europe over the last several years. In the United States, a return to the use of more platinum in autocatalysts for cars powered by gasoline began in late 1999and gained momentum in 2000. This trend was expected to continue, especially if the price of palladium remained above that of platinum. Demand for platinum metal in the industrial sector continued to increase; demand was expected to be up by more than 3,000 kilograms (kg). Increased platinum use in computer hard disks caused demand in electrical-electronics applications to increase substantially.

Growth in consumer demand for iridium by the glass industry for crucibles was more than offset by lower demand for use in autocatalysts.

Platinum-Group Metals in the 20th Century

At the beginning of the 20th century, the use of PGM in the United States was limited to the manufacture of laboratory ware, as a catalyst in the production of sulfuric and nitric acids, and in jewelry. Almost all U.S. production of PGM at that time was from placer deposits in the Goodnews Bay district of southwestern Alaska and gold placers in California. In Canada, platinum was produced as a byproduct of nickel copper-copper mining. In 1920, a large primary platinum deposit was discovered by Hans Merensky in a platiniferous reef in South Africa in the Bushveld Igneous Complex.

After an active period of placer mining and prospecting for precious metals, exploration for PGM in the United States essentially ceased in the early 1900s because of the availability of foreign supplies and the lack of directly applicable modern geologic, geothermal, and geophysical techniques for finding new deposits. U.S. production was less than 800 kilograms per year while consumption was estimated at about 9,000 kilograms. In the mid 1960s, analytical techniques for determining PGM in geologic materials at the low parts-per-billion level were developed. With a better understanding of the geochemistry and geology of the elements, modern programs of exploration began to find previously unknown occurrences of PGM. The most promising occurrences were found in Stillwater, Sweet Grass, and Park Counties in southern Montana. In the early 1970s, geologists discovered palladium and platinum along the J-M Reef in Stillwater County. In 1979, a partnership was formed to develop PGM discovered in the area. In 1986, underground mining operations began at the Stillwater property.

By 2000, the fundamental structure of the markets for palladium, platinum, and the other PGM changed substantially. World production had increased to about 365,000 kilograms. South Africa, Russia, and Canada remained the world's major producers while the United States became a minor source, producing about 13,400 kilograms in 2000. PGM-based catalytic converters, developed in the mid-1950s, had become required equipment on all automobiles manufactured in the United States. Autocatalysts were, by a significant margin, the largest end-use of PGM in the country, accounting for about 48,000 kilograms or 40% of consumption in 2000. Electrical and electronics, a major end-use in 2000, accounted for about 32,000 kilograms or 27% of overall PGM consumption. Jewelry, a major end use of platinum worldwide (especially in Japan), accounted for only about 8,000 kilograms (7%) of U.S. consumption in 2000. Another 44,000 kilograms (37%) of PGM were used in other domestic applications, including petroleum reforming catalysts, chemical process catalysts, dental and medical devices, and the glass industry.

Digitized by Google

Ruthenium pastes are used in the manufacture of resistors, which are found in all electronic devices. In 2000, sales of products such as mobile phones, computers, and video games pushed the output of resistors up by more than 30%. Also, prices were influenced by reports of a ruthenium-based material that will eventually permit hard disk drives to store 100 gigabits of data per square inch of disk area. Current technology is limited to data densities of 20 to 40 gigabits per square inch.

According to Johnson Matthey plc, global automobile demand for rhodium was expected to increase by 1,700 kg to 17,500 kg in 2000, boosted by higher vehicle production, tighter emissions standards, and changes in the PGM mix in autocatalysts. Stage III European emissions legislation came into force in 2000, leading to an increase in average rhodium loadings. Although European Union stage IV regulations will not take effect until 2005, fiscal incentives encouraged some car manufacturers to fit automobiles with catalysts capable of meeting stricter limits much sooner. Japan also saw an increase in rhodium demand in response to new legislation. Japan's Low Emissions Vehicle regulations were imposed in October 2000, but many automakers had adopted catalysts capable of meeting the new limits ahead of this deadline. Loadings on Japanese export vehicles have also increased, in line with tightening emissions limits in Europe and the United States (Johnson Matthey plc, 2000).

Legislation and Government Programs

In June 2000, the U.S. Defense Logistics Agency (DLA) requested the U.S. Mint to return 6,219 kg of platinum loaned in 1997 for the Mint's American Eagle Bullion program. DLA requested the return of the metal so that it could complete its fiscal year 2000 sales and prepare for its fiscal year 2001 sales. Under its Annual Materials Plan for fiscal year 2000, DLA was authorized to sell 3,888 kg of platinum. DLA was also authorized to sell the same amount of platinum in fiscal year 2001 and needs the material from the Mint to complete its sales. The terms of the 1997 agreement between the Mint and DLA required that a like amount of platinum of similar quality be returned before the agreement expires in 2003. If the occasion should arise, as it did in June 2000, the mint was required to return the metal upon 30 days notice. DLA requested that 50% of the material be returned by March 31, 2000, and the balance returned by June 30, 2000, so that the agency would be positioned to offer the material for sale by October 1, 2000 (Platt's Metals Week, 2000a). On August 25, DLA announced that the Annual Materials Plan for palladium would be increased by 3,110 kg for fiscal year 2000 and the Defense National Stockpile Center reactivated its PGM sales program on August 28, 2000.

Production

World mine production of PGM decreased by about 3%, to 365,000 kg compared with 376,000 kg in 1999. In South Africa, the world's leading producer, PGM output decreased by about 11% to 201,800 kg. Production in Russia, the world's second largest producer, was estimated to have increased by 11% to 128,100 kg.

The Stillwater Mining Co. operates the Stillwater Mine in Nye, MT. The company is the only primary palladium-platinum producer in the United States. In 2000, the Stillwater Mine reported production of 13,400 kg of palladium and platinum, over 5% higher than production in 1999. Of the 13,400 kg produced, palladium accounted for 10,300 kg, and platinum accounted for 3,110 kg. Mine production is defined by Stillwater as the quantity of PGM contained in a concentrate at the time it was shipped to the smelter. The company milled 617,000 metric tons of ore in 2000, 2% less than in 1999. The mill head grade was 21.5 grams per metric ton (g/t) of combined palladium and platinum in 2000, compared with 20.5 g/t in 1999. East Boulder, Stillwater's new mine, changed its focus in 2000 from surface construction to underground development. The concentrator and other surface facilities were essentially complete. During 2001, Stillwater expects to process a limited amount of ore through the concentrator from ore removed during the course of mine development work. Stillwater expected that the East Boulder Mine would move to commercial production during 2002 (Stillwater Mining Co., 2001, p. 9-14).

Stillwater operates a smelter and base metal refinery at its metallurgical complex in Columbus, MT. Expansions at the smelter were completed in 1999 and the smelter completed its first full year of operation in 2000. The smelter recorded a 12% increase in PGM produced, while reducing sulfur dioxide emissions by 67% compared with that of 1999. In the fourth quarter of 2000, the smelter shipped 445 kg of platinum and palladium contained in a matte, a quarterly record for the company.

Stillwater's automobile catalyst recycling effort also continued in 2000. The smelter processed more than 2metric tons per day of spent autocatalyst in 2000, containing 929 kg of palladium and platinum, more than double the 390 kg processed in 1999. Spent autocatalysts typically contain three parts platinum to one part palladium, reflecting the metals use in older clean-air technology. This ratio will shift in time as the palladium-dominated catalysts used in 1999-2000 begin to be recycled.

In 2000, Stillwater completed construction of a copper-dissolve-pressure-leach and selenium/tellurium removal circuits at its base-metal refinery. The function of the copper-dissolve-pressure-leach is to increase PGM production and provide ideal copper solution feed to the selenium/tellurium removal circuit. The selenium/tellurium circuit, as the name implies, removes selenium and tellurium from the copper solution that feeds a copper electrowinning circuit. The refining process removes small amounts of copper, gold, nickel, and rhodium to produce a final palladium-platinum product. A nickel sulfate crystallizer was also in the final stages of construction. Stillwater expected this circuit to be completed in the first half of 2001. The crystallizer will allow the company to ship its nickel sulfate byproduct as a solid rather than a liquid. The nickel sulfate is shipped to Canada for further refining. The final palladium-platinum product is shipped to California and New Jersey where it is converted into palladium and platinum sponge. The sponge is then sold, primarily for use in catalytic converters (Stillwater Mining Co., 2001, p. 18-21).

Proven and probable reserves of the company are contained in the J-M Reef in southern Montana. The average ratio of palladium to platinum contained in the reef is 3.3 to 1. At yearend 2000, proven and probable reserves, including the Stillwater and East Boulder Mines, contained 786,000 kg of palladium and platinum in 35.6 million metric tons (Mt) of ore grading 22.1 g/t of combined palladium and platinum.

Secondary production of PGM from spent autocatalysts and other PGM-bearing waste materials yielded increased amounts

Digitized by Google

of metal in 2000 when compared with that of 1999. Large amounts of platinum contained in catalytic converters from end-of-life vehicles helped push global recovered platinum from this source to 14,600 kg in 2000 versus 13,100 in 1999. U.S. secondary production of platinum was estimated at about 12,000 kg. Increasingly stringent regulations designed to reduce emissions prompted higher loadings of palladium in autocatalysts. Increased demand and short supplies prompted sharply higher prices and an attendant increase in the secondary recovery of palladium. About 7,200 kg were recovered globally in 2000, up from slightly more than 6,000 kg in 1999. Johnson Matthey reported that global recovery of rhodium from spent autocatalysts reached 2,430 kg in 2000, up 20% from 2,020 kg in 1999. The United States accounted for most of the increase, although significant increases were reported for Europe and Japan (Johnson Matthey plc, 2001, p. 49-52).

Consumption

In 2000, total world demand for platinum was up only slightly from 1999 and was estimated by Johnson Matthey at about 174,000 kg (Johnson Matthey plc, 2001, p. 48). U.S. apparent consumption of platinum was about 50,000 kg, or 28% of world demand. U.S. industry consumed an additional 12,000 kg of platinum that had been recovered from spent autocatalysts. World demand for palladium was down 3% from a near record 292,000 kg in 1999 to 277,000 kg in 2000. U.S. apparent consumption of palladium was estimated at 104,000 kg or 38% of world demand.

Platinum.—In 1999, demand for platinum by U.S. automakers declined for the third consecutive year, despite increased auto sales in the United States and Canada. Platinum demand declined because PGM loadings on catalytic converters had shifted toward palladium-rich catalysts. In 2000, demand for platinum in autocatalysts accounted for about 33% of total demand, growing by 14% to 57,200 kg. This was the first increase in 4 years for this sector of platinum demand. The increase was driven by automakers' efforts to reduce the palladium content in catalyst formulations and the move in Europe to diesel engines as new emissions standards are introduced. Platinum loaded autocatalysts are more efficient than palladium loaded catalysts on diesel engines. In the United States, there was a return to the use of platinum catalysts for gasoline engines. Automobile manufactures were under increasing pressure to reduce the amount of emissions from vehicles. In order to meet the new standards and keep prices down, automakers needed to reduce their dependence on the more expensive palladium.

Global demand for platinum in jewelry declined for the first time in 16 years, down by 1% to 88,300 kg. Increases of 15% in the United States, 16% in China, and a steady growth in Europe were more than offset by a 20% decline to 33,000 kg in Japan (Mining Journal, 2001a).

Palladium.—High prices had a negative impact on demand for palladium which declined by 9.7% to 277,000 kg. Higher prices had the greatest impact on the automobile sector where demand fell 12% to 161,000 kg. The electronics industry was also hit by high palladium prices, however, producers of multilayer ceramic capacitors (MLCC) were successful in replacing palladium with lower priced nickel and silver. Consequently, the proportion of MLCCs using palladium decreased from 62% in 1999 to 46% in 2000. Nevertheless, MLCC output rose by 47% in 2000, offsetting palladium's loss of market share. As a result, demand from the electronics sector increased by 5% to 64,400 kg. Although overall demand was down in 2000, it is important to note that supply was down as well, from 252,000 kg to 246,000 kg, mainly due to lower Russian sales. Global demand exceeded global supply by 14,900 kg (CRU Quarterly Market Service Report, 2001).

Rhodium.—The rhodium market was characterized by strong consumer demand and tight supplies. Demand for rhodium increased in all regions, driven by the need to meet tougher emission standards in Europe, Japan, and the United States. Rhodium was added to some palladium-only catalyst systems to meet more rigorous emissions control standards, as automakers attempted to minimize their dependence on palladium. New legislation coming into effect over the next few years is directed at hydrocarbon emissions for which palladium is particularly effective as a catalyst. The addition of rhodium to palladium-only catalyst, however, helps lower the overall PGM loading. Autocatalysts accounted for more than 90% of demand. Rhodium's other principal applications were in the manufacture of specialty chemicals and the glass industry. Sales to the glass industry, 1,300 kg, were strong in 2000, driven by the construction of new plants to manufacture the high-quality thin glass used in liquid crystal displays. Johnson Matthey estimates world demand for rhodium in 2000 at about 25,000 kg, 98% of which was used in autocatalysts. The amount of rhodium recovered from scrapped catalytic converters increased 20% to 2,400 kg, more than one-half of which were removed from cars in the United States, where rhodium levels in autocatalysts increased significantly in the early 1990s.

Iridium and Ruthenium.—Demand for ruthenium remained strong in 2000 as it was used in a new process that manufactured feed stock for the production of solvents and synthetic fibers. Consumption of ruthenium in catalysts used in the Kellogg advanced ammonia process was also strong in 2000. The process required less stringent operating conditions than traditional base metal catalysts, and thus substantially reduced energy costs.

Continuing growth in the electronics industry was the driving force in increased demand for both iridium and ruthenium. The largest consumption of ruthenium was in the production thick film paste used in the manufacture of resistors. Increased production of resistors, for use in consumer electronics, was somewhat offset by the miniaturization of electronic components.

Reduced sales of iridium automobile and chemical-process catalysts were more than offset by strong demand for crucibles for growing synthetic crystals, especially single crystal sapphires. During 2000, there was significant growth in the demand for mobile phones with production of these devices growing by almost 50%. This generated a comparable demand for lithium-based crystals, which are used in surface acoustic wave filters to prevent signal interference between individual phones. These crystals are grown in iridium crucibles. There was a significant increase in production capacity of these crystals in 2000 which led to an almost threefold increase in iridium consumption in this application.

The electrochemical industry accounts for significant portions of total demand for iridium and ruthenium. Electrodes coated with either iridium or ruthenium or a mixture of iridium and ruthenium are used in a number of electrochemical processes. The most important of these is the chlor-alkali process which is

Digitized by Google

used to produce chlorine and caustic soda from brine.

Prices

Russian shipments of PGM were delayed again in 2000, exerting upward pressure on PGM prices. Concern about supplies continued to run high as late as May when Russia resumed sales on a spot basis. Russia had offered spot palladium in the first few weeks of 2000 and resumed offering spot platinum in May. Even though Russia returned to the spot market, it remained silent about whether it would supply PGM under long-term contracts. Russia supplies more than 60% of the world's palladium and about 25% of the world's platinum.

Palladium.—The palladium price set an alltime record in 2000, ending the year at an average of $691.84 per ounce. After starting the year at $437, the price began to rise later in January, stimulated by strong demand and a shortage of the metal from Russia. Price increases steepened in February, reaching $815 on February 22. This gain was mostly due to panic buying on the Tokyo Commodities Exchange (TOCOM). On February 23, TOCOM suspended trading of palladium futures and froze prices to allow the orderly liquidation of contracts. On February 24, the palladium price fell abruptly below $700. The price decline was short lived, owing to continued shortages of physical metal, which supported a palladium price above $700 for much of March. Prices began to sink again following rumors of imminent shipments from Russia, falling to around $570 on March 31. Prices began to climb in April, encouraged by strong physical demand, an increase in lease rates, and the cancellation of TOCOM restrictions on palladium contracts. The rally continued, culminating on August 2, when the price of palladium reached a new high of $865. The rally ended quickly as prices fell to $720 on August 28. Palladium prices made even more dramatic gains in December when it was reported that RAO Norilsk Nickel had exhausted its palladium export quota for 2000 and that the Russian Government had no plans to sell more metal. The price climbed rapidly above $900, finally reaching a record high of $985 on December 27.

Platinum.—Platinum prices advanced strongly in 2000, rising from a low of $416 per ounce on January 6 and closing the year at an average $549.31 per ounce. The low was in response to reports that the President of Russia had signed a revision to a clause in the 1999 budget bill that provided the legal framework for the resumption of platinum exports. Platinum exports had been delayed since April 1999. Prices began to rise during the middle of January as it became clear that, despite the revision, shipments from Russia would not resume immediately. Prices continued to climb through February, reaching an 11-year high of $573 on February 17. Prices fell to around $460 in the first week of March and experienced wide swings in April before settling between $470 and $570 through July. Prices increased sharply again in August, driven by lack of shipments from Russia and lifted by palladium's record price. On August 2, the platinum price reached $615, its highest level since 1988. The rally ended abruptly as reports circulated that Norilsk Nickel expected to ship metal to Japan in September or October. Prices made gains in September, rising above $600 on several occasions, but began to weaken again in mid-September, falling to a low of $582 on September 26. Prices began to rise again in early November reaching $625 on the 28th. Again the increase was driven by a shortage of physical metal supplies from Russia. The increases continued into December with prices reaching $625 on the 13th and again on the 28th, its highest price since August 1987. Prices continued to trade above $600 for the remainder of the year.

Iridium, Rhodium, and Ruthenium.—Strong consumer demand and short physical supplies pushed the price of rhodium to an 8-year high of $2,600 per ounce in August 2000. Increased sales from Russia caused prices to weaken to $1,625 in October, before recovering to $2,025 at yearend. Industrial buying propelled the price of ruthenium to a high of $170 per ounce in August, but iridium was unchanged at $415 per ounce throughout the year (Johnson Matthey plc, 2001, p. 45-46).

Trade

In 2000, U.S. net import reliance as a percentage of apparent consumption was estimated at 89% for palladium and 83% for platinum. South Africa accounted for 64% of refined platinum and 12% of refined palladium imports; Russia accounted for 51% of refined palladium and 3% of refined platinum imports. Palladium imports decreased 4% to 182,000 kg from 189,000 kg in 1999; platinum imports were down 25% in 2000 to 94,000 kg from 125,000 kg in 1999. U.S. exports were 58,600 kg of palladium, 25,000 kg of platinum, and small amounts of other PGM.

World Review

Russia.—Russian sales of platinum and rhodium increased in 2000 following the resolution of policy issues that had prevented exports for much of 1999. The policy restricted PGM exports to authorized "State Organs." Russia's sole PGM exporter, Almazjuvelirexport, did not fit this description and neither did any other Russian organization (Platt's Metals Week, 2000c). Palladium sales were less affected in 1999 because Norilsk Nickel, Russia's primary PGM producer, had been given a 10-year quota and export license for its product. Although Russia does not publish its PGM statistics, it is generally accepted by the industry that Norilsk Nickel has an annual output of 20 to 22 metric tons per year (t/yr). Norilsk has an annual quota, authorized by the Government, to export its platinum (also palladium and rhodium), and it receives the world market value from buyers. This policy does not apply to other Russian producers. Koryakgeoldobycha (KGD), Russia's leading alluvial producer, and other alluvial producers concentrated in the Russian Far East account for about 10 t/yr of PGM output (Platt's Metals Week, 2000b). Gokhran, the State metal stocking agency, has a pricing policy that offered alluvial producers 20% to 30% less than the international market value for their metal. This discrepancy led to a dispute between the alluvial platinum producers and Gokhran, as the producers refused to sell at Gokhran's price. KGD began stockpiling its platinum rather than sell to Gokhran. KGD reportedly has a large stockpile unsold from 2000 and plans to hold up to 2,200 kg of platinum while it waits for a change in State pricing policy. Gokhran has not announced any changes in its pricing policy. Meanwhile, KGD planned to increase its platinum output to 4,400 kg in 2001 from 3,300 kg in 2000. The company is also asked the Government for permission to export its metal without having to go through Gokhran (Platt's Metals Week, 2000b).

South Africa.—Along with byproduct cobalt, copper, gold, nickel, and silver, PGM occurs in South Africa in three separate

Digitized by Google

layered reefs associated with mafic rocks in the Rustenburg Layered Suite of the Bushveld Complex in the Transvaal. The reefs are the Merensky Reef, the UG2 Chromite Layer, and the Platreef. The PGM occurs as alloyed native metals, as platinoid minerals (such as sperrylite and braggite) and in copper, nickel, cobalt, and iron sulfide minerals (such as chalcopyrite, pentlandite, and pyrrhotite).

Rustenburg Platinum Mines Ltd. (RPM), a subsidiary of Anglo American Platinum Corp., Ltd., was the largest single South African PGM producer and operated three geographically separate sections, all on the western limb of the Bushveld Complex. The other mines on the western limb are the two adjoining Impala Platinum Ltd. (Implats) Mines, Bafokeng North Mine and Wildebeestfontein South; the two Lonmin Platinum Division mines, Eastern Platinum Ltd. and Western Platinum Ltd.; and Northam Platinum Ltd. (Department of Minerals and Energy, 1997, p. 34-36).

In 2000, South Africa produced about 201,800 kg of PGM, about 11% less than the 224,600 kg produced in 1999. Production fell because of a combination of heavy rainfall and strike actions at Anglo American Platinum, the world's leading producer of PGM. Production of platinum at Anglo Platinum fell by 4,700 kg to 58,200 kg. Implats' production was also impacted by the heavy rains. Although mining itself was unaffected by the poor weather, the collapse of a conveyor belt disrupted mineral processing and was the main reason for a 2,330 kg drop in output to 31,100 kg. Lonmin, plc, which is further east, and was less affected by the inclement weather, increased production by 4% to 20,200 kg. Northam Platinum Ltd. output was virtually unchanged at 5,510 kg while Kroondal, which completed its first year of full production, produced 2,000 kg of platinum (Mining Journal, 2001b).

The positive outlook for PGM markets resulted in a number of expansion plans by South African producers. Anglo American Platinum announced that it would invest R12 billion to expand output from 62,200 kg to 109,000 kilograms per year (kg/yr) of refined platinum by 2006. Of the announced expansions, those at the Amandelbult Mine and Lebowa Mine, with a combined output of 3,330 kg, were completed in 2000. A new mine, costing R1.3 billion in Maandagshoek, with a production capacity of about 5,000 kg/yr of platinum, was scheduled to come into operation by 2004 (Metal Bulletin, 2000a).

Implats reopened the Crocodile River Mine and opencast mining began in December 2000. At full production, the mine's platinum output reportedly will be 1,600 kg/yr. In December 2000, the company announced its purchase of 100% of Platexco, Inc., a Canadian listed company that owns the Winnaarshoek property on the eastern limb of the Bushveld Complex. Mining is expected to begin in 2002, and full production of 6,220 kg/yr of platinum is planned for the end of 2003 (Mining Journal, 2001).

The Kroondal platinum mine in South Africa planned to triple production of PGM to 15,900 kg/yr in a joint venture with Amplats. Kroondal started commercial production in September 1999, and reached full production within 3 months. Under the proposed joint venture, RPM will contribute portions of its UG2-reef mineral rights, while RPM will contribute the existing mine and plant as well as its own mineral rights. The mineral rights contribution from RPM will lift the projects *in situ* resources to nearly 60 Mt of UG2 ore, and is designed to ensure a mine life of 13 years. The partners intend to expand the existing plant from its current design capacity of 5,290 kg of PGM (3,110 kg/yr of platinum 1,680 kg of palladium, and 498 kg of rhodium) to 7,930 kg/yr of PGM per year, including 4,670 kg of platinum. A new concentrator, which will be built next to the mine's eastern decline, will have a similar capacity, boosting Kroondal's annual output by 1,590 kg (9,330 kg platinum) from a total feed of 5.4 Mt of ore (Mining Journal, 2000).

Zimbabwe.—In 1999, Zimbabwe produced about 7,200 kg of PGM but its major primary producer, Hartley Platinum, was closed in June 2000. Following the closure of Hartley, Zimbabwe's only primary production came from the small Mimosa Mine, with an output of about 600 kg/yr. Mining investments in Zimbabwe have often been discouraged by political and economic instability. In 2000, there was the prospect of a new framework for investing in platinum mining, with the Government expected to relax foreign exchange restrictions and reduce the tax rate on platinum operations. An improved climate for investment will likely lead to funding for the development of the Ngezi opencast mine. Zimbabwe Platinum Mines Ltd. (Zimplats), which owns the mine, reported that it had carried out a 3-month trial mining program at Ngezi and full-scale mining would begin as soon as new mining legislation is passed. The Ngezi platinum mine is expected to produce a minimum 2 million metric tons per year (Mt/yr) of unrefined ore. A 2 Mt/yr mining rate is considered a minimum and, if the project proceeds, the tonnage is expected to increase. The mine processing plant would consist of a conventional crusher, mill, concentrator, and dryer. Dried metal in sulfide concentrate would be the mine end-product for sale or toll refining of the contained palladium, platinum, copper, nickel, and gold. Zimplats is also interested in restarting activities at the closed Hartley platinum mine and an agreement has been reached by Zimplats and the Zimbabwe Government on the takeover. Zimplats owned a 33.3% share in Australia-based Broken Hill Proprietary Co. Ltd. before the company closed Hartley (Metal Bulletin, 2000b).

Current Research and Technology

Palladium-Silver Resistors for High-Power Applications.—With the advent of ruthenium-based resistors, the use of palladium-silver resistors on thick film circuits was all but discontinued until the 1990s when demand in new niche applications led to their resurgence. The relatively high power-handling of these metallic resistors enabled them to be used as secondary lightening surge protection devices for communications equipment. For such applications, low-value compositions, about 0.1 to 1 ohm-milimeter^2/centimeter (Ω/□), are printed in a serpentine configuration, typically about 1.27-centimeter (cm) x 2.54-cm area, to fabricate 10-to 300-ohm components. More recently, the resistance range of interest to circuit designers has shifted down to as low as 5.6 ohms. Although it is possible to design 5.6-ohm resistors using the existing 0.1 Ω/□-inks, the resulting area would be quite large, resulting in bulky circuits. This points to a need for low resistivity inks with more robust power handling capability. A new series of palladium-silver inks with resistivity as low as 0.015 Ω/□ have been developed. The palladium-silver resistors can extend the reach of thick film technology into high power applications that were formerly reserved for bulky wire-wound resistors (Printed Circuit Design, 2000).

Advances in PEM Fuel Cells.—Under terms of an agreement

Digitized by Google

between Johnson Matthey and James Cropper plc, Technical Fibre Products, the advanced composites subsidiary of James Cropper, will provide key components in Johnson Matthey's new Membrane Electrode Assembly (MEA) products for fuel cells. The agreement centers upon the development of carbon composite substrates to be used to support the [platinum] catalysts and other MEA components that form the heart of polymer electrolyte membrane (PEM) fuel cells. There now seems little doubt that fuel cells will emerge as a major propulsion system for cars and trucks within the next 5 to 10 years and will generate an additional demand for about 500,000 kg of platinum. Offering an attractive driving range and quick refueling, fuel cells may displace various high-energy battery options that are now being investigated to meet zero emission requirements on vehicles in the United States (Platt's Metals Week, 2000b).

Currently, fuel cell power units cost about 10 times that of conventional gasoline engines and use hydrogen (liquid or gas) as the primary fuel. Most researchers in the field, however, have begun investigating alternatives to pure hydrogen as the primary fuel because of difficulties associated with its storage and distribution and are considering the use of methanol. Methanol is low in carbon and rich in hydrogen. Fuel cell power systems fueled by methanol would require a reformer subsystem to convert methanol to the hydrogen required. One disadvantage of methanol is that, unlike the use of pure hydrogen, water would not be the only exhaust pipe emission; carbon monoxide, carbon dioxide, and nitrogen oxides would also be emitted (Metal Bulletin Monthly, 2000). In a related project, researchers at NASA's Jet Propulsion Laboratory, Pasadena, CA, have developed an improved method of fabricating PEM-electrode structures for methanol fuel cells. The procedure involves the use of improved sprayers to deposit inks containing [platinum] catalytic metals onto proton exchange membranes of perflurosulfonic acid polymers. The inks usually contain the catalytic metal (platinum for the cathode and a mixture of platinum and ruthenium for the anode), a proton conducting ionomer solution, water, and isopropanol, with perhaps a small amount of a polytetrafluoroethylene-based additive. In experiments, the performances of fuel cells containing electrode structures made by the new method were found to be comparable to fuel cells made by older methods. The amount of catalyst used in the new method, however, ranged from 1 to 2 milligrams per square centimeter (mg/cm^2), whereas the amounts used in the older methods were typically about 4 mg/cm^2. The new method is suitable for mass production and may be a significant step toward commercialization and reducing the cost of fuel cells (NASA Tech Briefs, 2000).

New Fuel Cell May Eliminates Need for Platinum.—The most commonly used fuel cells contain platinum catalysts to convert conventional fuels into hydrogen fuel. Researchers in Japan have designed a solid-oxide fuel cell (SOFC) that advances the prospect of using fuel cells for onboard power generation in transportation applications that require the use of conventional fuels. The system consists of only one gas chamber in which both the anode and cathode are exposed to the same mixture of fuel and air. This design eliminates the need for a reformer, which uses a platinum catalyst, to convert hydrogen rich hydrocarbons to hydrogen. SOFCs have several advantages over more commonly used PEM fuel cells. For example, SOFCs do not require conversion of hydrocarbons to hydrogen, and SOFCs have a lower fabrication cost because they do not require the use of platinum catalysts. In addition, the anode in SOFCs is not poisoned by carbon monoxide, a major problem with PEM fuel cells that decrease their performance when conventional fuels are used directly. The new SOFC design also is compact and takes up less space than PEM cells. That advantage, combined with no need for an onboard reformer, makes the SOFC system attractive for transportation applications (Environmental Science & Technology, 2000, p. 419A).

Outlook

Despite the forecast of reduced world economic activity, demand for platinum is expected to continue to increase. Future demand is expected to be influenced by the automobile industry as sales of diesel powered vehicles increase in Europe and Japanese and U.S. automakers add platinum to autocatalyst on gasoline engines in an effort to reduce their dependence on palladium. Jewelry manufacturing, which accounts for a major portion of platinum demand, is expected to weaken in 2001. Weak economies in Japan coupled with high prices over the past year caused demand at the lower end of the jewelry market to shift to cheaper materials, such as white gold. Demand for platinum jewelry in China was on the rise, increasing 22% to 34,200 kg in 2000. China, second largest jewelry consuming market after Japan, imports most of its demand for platinum and may strengthen controls over imports to discourage illegal trading (China Metal Market, 2001). Demand for platinum in industrial applications is expected to rise but at a slower rate than in the previous 2 to 3 years owing to a decline in world economic conditions.

Rising palladium prices in 1999-2000 led to increased substitution of base metals for palladium in the electronics and dental industries, and automakers made clear their intentions to reduce dependence on the metal. Despite substitutions and further loss of market share in multilayer ceramic capacitors, palladium demand actually increased in this sector. The electronic device market appears to be in a downturn and electronic component manufacturers are beginning to cut back production. Thus, demand for palladium from this sector will likely fall in the next 1 to 2 years and palladium prices will drop back to historical levels.

e/ Estimated. r/ Revised.

1/ World totals, U.S. data, and estimated data have been rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through April 27, 2001. Platinum-group metal (PGM) production by Germany, Norway, and the United Kingdom is not included in this table because the production is derived wholly from imported metallurgical products and to include it would result in double counting.

3/ In addition to the countries listed, China, Indonesia, and the Philippines are believed to produce PGM, and several other countries may also do so, but output is not reported quantitatively, and there is no reliable basis for the formulation of estimates of output levels. A part of this output not specifically reported by country is, however presumably included in this table credited to Japan.

4/ PGM recovered from nickel ore that is processed domestically. PGM in exported nickel ore are extracted in the importing countries, such as Japan, and are believed to be included in the production figures for those countries.

5/ Production derived entirely from imported ores.

6/ Reported figure.

7/ A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

POTASH

By James P. Searls

Domestic survey data and tables were prepared by Joseph M. Krisanda, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

Potash denotes a variety of mined and manufactured salts, all containing the element potassium in water-soluble form. At the end of the 19th century, potash was made from hardwood trees and was a mixture of potassium carbonate and potassium hydroxide, both of which are caustic. Lye meant sodium hydroxide, and potash lye was potassium hydroxide, a higher grade product that made a better (softer, facial) grade of soap. Since approximately 1950, the term potash has been used to indicate potassium chloride (KCl, sylvite), potassium sulfate [K_2SO_4, or sulfate of potash (SOP), sometimes a manufactured product], and potassium-magnesium sulfate [$K_2SO_4 \cdot 2MgSO_4$ or langbeinite or sulfate of potash magnesia (SOPM or K-Mag)]. Muriate of potash (MOP) is an acceptable mix of potassium chloride (95% or higher) and sodium chloride that includes minor amounts of other nontoxic minerals of the mined ore for fertilizer use and is neither the crude ore sylvinite nor pure sylvite. This publication has historically included potassium nitrate (KNO_3 or saltpeter, a manufactured product) or mixed sodium-potassium nitrate ($NaNO_3 + KNO_3$ or Chilean saltpeter, a natural product) because it functions as a potassic fertilizer. Saltpeter and Chilean saltpeter are still noted in the import tables (tables 8, 9). Alunite, feldspar, and muscovite are potassium-bearing minerals that are quite insoluble in water and are considered to be neither potassic fertilizers nor ores for price-competitive potassic fertilizers.

Potash is used primarily as an agricultural fertilizer (plant nutrient) because it is a source of soluble potassium, one of the three primary plant nutrients (the others are fixed nitrogen and soluble phosphorus). Potash and phosphorus are mined products, and fixed nitrogen is produced from the atmosphere by using industrial processes. Modern agricultural practice uses large amounts of these primary nutrients plus such additional nutrients as boron, calcium, chlorine, copper, iron, magnesium, manganese, molybdenum, sulfur, and zinc to ensure plant health and proper maturation. The three major plant nutrients have no substitutes, but low-nutrient-content alternative sources of plant nutrients, such as animal manure and guano, bone meal, compost, glauconite, and "tankage" from slaughterhouses, can be used. In addition, KCl is important in industrialized economies where it is used in oil well drilling mud, aluminum recycling processes, a steel heat-treating process, metal electroplating, snow and ice melting, and water softening. Potassium chloride may be used in the chlor-alkali industry to produce potassium hydroxide. The alkali potassium hydroxide is the precursor of potassium carbonate and is used for industrial water treatment, for producing potassium phosphates, and in soap manufacture. The alkaline salt potassium carbonate is used in the glass for television and computer monitor tube production, alkaline batteries, food products, pharmaceutical preparations, photography, some fire extinguishers, animal feed supplements, and as a catalyst for synthetic rubber manufacture. Generally, these uses have accounted for no more than 10% of the annual consumption in the United States, but this percentage varies because industrial end uses tend to vary with the domestic economy, whereas fertilizer end uses tend to vary with disparate world weather patterns, world demand, relative currency values, and other countries' economic gyrations and their ability to pay for either fertilizers or food stuffs.

Legislation and Government Programs

The 1993, a class-action potash antitrust lawsuit was filed in

Potash in the 20th Century

At the beginning of the 20th century potash was used for glassmaking, soapmaking, bleach, and making saltpeter. It was a fertilizer to such very high value crops as tobacco and cotton. In 1870, a mineral source of water-soluble potassium ore named "carnallite" had been found near Stassfurt, Germany, from which the vaunted German chemical industry learned to separate potassium chloride (KCl). During the First World War, there were no imports from Germany. Potassium was needed for the solid oxidizer potassium permanganate in First World War gas masks and as potassium nitrate, an oxidizer in the munitions and signaling rockets. The price of potash rose to $600 per ton measured in 1916 dollars. Potassic salts were extracted from subsurface Searles Lake brines in California, some Nebraska lake brines, the dust of cement plants, iron refinery dust in Pennsylvania, molasses refinery waste in Maryland, old-fashioned tree ashes in Michigan and Wisconsin, and kelp (seaweed) off the coast of California. After the war, Congress allocated money to find reasonably priced potash in the United States. In 1925, an oil exploration team in New Mexico noted sylvinite in a well east of Carlsbad, NM. Potash production as KCl commenced in New Mexico in 1932. Three mines were operating in the New Mexico Known Potash Resource Area by the beginning of the Second World War. The New Mexico reserves were seen to be finite in the 1950s as more mines started up, and after searching likely sedimentary basins in the United States, potash mine owners moved up to a showing of sylvinite in Saskatchewan, Canada. With difficulty, a huge high-grade resource of sylvinite was changed to reserves through technology. The year of peak U.S. potash production was 1966, as Canadian potash started to enter the U.S. market.

At the end of the 20th century, Canada provided approximately 90% of the KCl consumed in the United States.

many places and consolidated to the U.S. District Court for Minnesota in Minneapolis, MN; it was dismissed by summary judgment in January 1997, except for a California State Court lawsuit which allows indirect consumers to participate and is treated differently, and an Illinois State Court complaint of antitrust. An appeal to the U.S. Court of Appeals for the Eighth Circuit resulted in affirmation of dismissal for some of the defendants and a divided decision reversing the dismissal for some of the other defendants. These latter defendants reargued the case before the U.S. Court of Appeals for the Eighth Circuit in September 1999, and the court of appeals affirmed the dismissal of the complaint for all defendants by summary judgment on February 17, 2000. The plaintiffs appealed to the U.S. Supreme Court for review through a writ of certiori, which was denied without comment on October 2, 2000 (Potash Corp. of Saskatchewan, Inc., 2001a). According to the same Securities and Exchange Commission filing, the California State Court lawsuit was dismissed by the end of the year, as was the Illinois State Court complaint.

Production

Production of all types and grades of potash in the United States could not be accurately published in 2000 because of proprietary data constraints. Production increased moderately compared with that of 1999 (table 1).

The U.S. Geological Survey (USGS) developed domestic potash data from voluntary semiannual surveys of U.S. operations. Of the seven survey requests sent to operations for both semiannual surveys, six operations responded. Data were estimated for the nonrespondent for both surveys. Data from the responding sites were estimated to represent about 98% of the total production listed in table 1.

Four U.S. companies produce potash in three States. Most of the domestic production was from southeastern New Mexico, where two companies operated three mines. The other two States with potash production were Michigan and Utah. One New Mexico producer also owned a Utah surface brine operation and a deep solution mine in Michigan. Potash producers in the United States produced KCl, SOP, and SOPM. Potassium nitrate was manufactured in the United States, but output is not reported in this publication because it is a manufactured material rather than a mined material. Because all four companies produced standard and granular MOP, prices for those products were reported. All of the domestic production of SOP and SOPM, together known as sulfates, came from a single company, which prevents publishing data that could reveal or allow calculation of sulfates production, sales, or stocks.

Domestic potash sales were essentially unchanged (as K_2O) from that of 1999 owing to a moderate rise in apparent consumption, a moderate rise in imports, and a moderate decline in exports.

IMC Kalium Ltd. of IMC Global Inc. produced MOP, SOP, and SOPM in Carlsbad, NM, at the operation that started in 1940 and now includes the former Western Ag-Mineral Mine property. It also produces MOP from the Hersey, MI, solution-mine and plant and SOP from the brines of Great Salt Lake near Ogden, UT. In Carlsbad, IMC Global's new SOPM processing plant was operating with ore from its original leases and the former Western Ag-Mineral leases. It was built near an older mine shaft with its own ore hoisting facility and a separate underground conveyor belt. Only SOPM ore was hoisted up this shaft, and only sylvinite (KCl ore) was hoisted up the original shaft. Mississippi Potash, Inc., a subsidiary of Mississippi Chemical Corp., produced MOP from two potash operations near Carlsbad, known as Mississippi Potash East and Mississippi Potash West. Mississippi Potash, Inc., also operated the augmented compacting facility at the former National Potash Co. mill site known as Mississippi Potash North to convert standard MOP to granular MOP for its market.

In Utah, Reilly-Wendover Division's near-surface brine operation of Reilly Industries, Inc., continued production of MOP and manure salts. The Moab Salt, LLC, solution mine and mill continued production of MOP and table salt for Intrepid Mining, LLC, of Denver, CO. IMC Kalium Ogden Corp. continued to produce SOP from brines of Great Salt Lake through the use of solar evaporation ponds and some beneficiation in the adjacent plant. IMC Kalium Ogden's operation was offered for sale along with IMC Chemicals and IMC Salt in the middle of the year (North American Minerals News, 2000b).

In Michigan, IMC Potash Hersey Inc. operation produced white MOP from deep wells (deeper than 2,000 meters) and solution mining through mechanical evaporators and crystallizers.

The fertilizer industry has joined the latest electronic age time-saver technology with the initiation of business-to-business relationships. There are at least two such groups (Rooster.com and planetAG.com) in the United States and another forming in Germany (mySAP.com). At home, on their computers, farmers can "...market their crops, and buy their seed, fertilizers, crop protection products, equipment[,] and other supplies" (Green Markets, 2000d).

Consumption

The apparent consumption of potash for 2000 in the United States was estimated to have increased by less than 5% from that of 1999 to about 5.6 million metric tons (Mt). In 2000, as in several other years, the variation in demand for potash in the United States was controlled by forces other than the direct demand for domestic or exported farm crops, especially grain crops, or the relatively moderate price of potash. As the price rise of natural gas drove up the price of fixed nitrogen fertilizers and nitrogen/phosphate fertilizers, sales and application of these natural-gas-based fertilizers suffered. Since the three fertilizers have to be balanced in the soil for the most profitable investment for crop production, potash sales did not rise as much as they might have.

Fertilizer is an input into agriculture, and a reasonable description of potash demand can be given through the largest crops, which are corn for grain, soybeans for beans, and sorghum, rice, and cotton of all types. Corn, soybeans, and cotton showed increased planted area in 2000, up by a few percent compared with that of 1999, and area harvested was up by a few percent with yield and production increased by a few percent (National Agricultural Statistics Service, 2000, p. 4-5, 7, 10-11; 2001b, p. 1). Average corn yield was the second best yield rate on record, and total production was the second highest on record. Domestic corn consumption was boosted by two end uses: the increased production of ethanol owing to the increased domestic price of gasoline, and the increased exports of prepared meats, from cattle, pork, and poultry fed on domestic grains. The prepared meat markets—beef and pork to

Digitized by Google

Japan and chicken to Hong Kong and Russia—rose owing to the Asian Pacific Basin's return to financial health and the increase of Russia's consumer demand for meat. Corn exports declined but to a lesser extent owing to lower corn production in China, Eastern Europe, North Africa, and the Middle East due to adverse weather. Ending corn stocks in the United States were up by nearly 6% to 216.4 Mt (National Agricultural Statistics Service, 2001c, p. 1, 5). Soybean production for beans was the highest on record (National Agricultural Statistics Service, 2001a, p. 10), soybean exports soared nearly 17% (Economic Research Service, 2001), and ending U.S. soybean stocks were up by about 2.6% (National Agricultural Statistics Service, 2001c, p. 5). The wheat-of-all-types planted area was unchanged from 1999, and area harvested decreased by 1.5%, while yield per hectare declined by 1.7% owing to dry weather in the southern plains, amounting to a 3.3% decline in production, the only yield-declining major crop in 2000 (National Agricultural Statistics Service, 2001b, p. 1, 5). Wheat exports declined by about 2% (Economic Research Service, 2001, p. 2). Ending U.S. wheat stocks (all wheat in all positions) declined by 4.4% to 49 Mt (National Agricultural Statistics Service, 2001c, p. 1, 5). U.S. grain exports were lower except for soybeans and sorghum (Economic Research Service, 2001, p. 2-3). Sorghum and rice production declined in 2000 by 21% and 7%, respectively (National Agricultural Statistics Service, 2001b, p. 14). Cotton yield increased about 4% per acre and production increased by about 1.5% (National Agricultural Statistics Service, 2000, p. 10-11; 2001b, p. 10). Cotton and cotton linters exports increased by more than double (Economic Research Service, 2001, p. 4).

Mexico was reported to be an important importer of U.S. wheat, corn, soybeans, and cotton owing to its increased earnings from the elevated price of oil. For U.S. agricultural exports, Mexico was reported to be the second largest receiver, with Japan being the largest, in agricultural bulk commodities, and fourth for high-value products (Economic Research Service, 2001, p. 5). [High value products are all agricultural products minus bulk commodities.]

Generally, potash demand was up slightly but without a clear agricultural commodity or an importing country that made a large difference. The farmers produced more corn, cotton, and soybeans using a lesser amount of potash, which might mean that genetically modified seed was more efficient at using the agricultural inputs, such as acreage, fertilizer, rain, etc., than unmodified seed.

All U.S. grain prices were relatively low, but "[d]irect government payments to farmers rose from [less than] $8 billion in 1997 to a record $22 billion last year [2000]" (Collins, 2001).

According to Potash & Phosphate Institute data, agricultural MOP shipments from Canadian and U.S. producers to the major destination by State, in decreasing order of tonnage, were Illinois, Iowa, Indiana, Ohio, Missouri, Minnesota, Wisconsin, Michigan, Florida, and Tennessee (table 3). These 10 States received 65% of agricultural sales of MOP from Canadian and United States producers in 2000. For agricultural and nonagricultural MOP shipments from Canadian and United States producers, the major receiving States, in decreasing order, were Illinois, Ohio, Iowa, Indiana, Alabama, Wisconsin, Missouri, Minnesota, Michigan, and Florida. These 10 States received about 64% of agricultural and nonagricultural sales of MOP in 2000.

The major destinations for agricultural MOP shipments from U.S. producers, in decreasing order, were Texas, Missouri, Michigan, California, Illinois, Kansas, Nebraska, and Iowa. These eight States consumed about 80% of the MOP from domestic producers. For agricultural and nonagricultural MOP sales from U.S. producers, the major receiving States, in decreasing order, were Texas, Missouri, Michigan, California, Illinois, Mississippi, Kansas, Iowa, Nebraska, and New Mexico. These 10 States received about 80% of U.S.-produced agricultural and nonagricultural MOP.

Foreign Trade

Based on U.S. Census Bureau data, as modified by the USGS, the exports of all types and all grades of potash decreased by 20% to 367,000 metric tons (t) from 459,000 t in 1999 (table 6). Exports of MOP totaled about 49% of all potash exports, SOPM totaled about 27%, SOP totaled about 21%, and potassium nitrate totaled about 3%. Latin America received about 64% of all exports, the Pacific Basin received about 25%, with the remaining 11% distributed among Africa, Canada, Europe, and the Middle East.

U.S. MOP exports fell by 36% to 181,000 t from the 1999 total of 282,000 t. MOP exports decreased by 32% to Latin America, 98% to Europe, and 21% to the Pacific Basin. SOP exports increased by about 12% to 78,000 t from 68,000 t with stronger first half-year sales. SOP exports to the Pacific Basin rose by 76% to 43,000 t, and SOP exports to Latin America fell by 8% to 35,000 t. The Pacific Basin received about 55% of total SOP exports, while Latin America received about 45%. Total exports of SOPM were essentially unchanged from last year, with Canada increasing its imports by 27%, and imports to Latin America and the Pacific Basin declining by about 14% and about 4%, respectively.

Potash imports into the United States increased by about 3% compared with those of 1999 to about 4.6 Mt (tables 8, 9). MOP imports from Belarus, Canada, and Russia increased slightly. SOP imports from Canada, Chile, and Germany decreased. Potassium nitrate imports from Chile nearly doubled. MOP accounted for nearly 99% of total imports, and Canada supplied about 94% of the MOP imports.

Transportation

The U.S. Surface Transportation Board (STB) held hearings on the proposed merger of Burlington Northern and Santa Fe Railway Co. with Canadian National Railway Co., Grand Trunk Western Railroad Inc., and Illinois Central Railroad Co. The STB then put all mergers on hold because of railroad freight customers concerns that another large merger would again bring traffic to slow motion after the experience of the previous merger of the Union Pacific and Southern Pacific Railroads in 1997 and 1998 (Green Markets, 2000e) and the problematic division of Consolidated Railroad Corp. (CONRAIL) into a section for Norfolk Southern Corp. and a section for CSX Corp. in 1999.

A new bulk fertilizer terminal in the sea port of St. Petersburg, Russia, has been proposed with the help of the joint stock corporation (JSC) Uralkali of Berezniki, Perm, Russia (Fertilizer Week, 2000d).

World Review

Estimated world potash production for 2000 declined by

Digitized by Google

about 1% from that of 1999 (table 10). European production was down by 1% with production in Germany and Spain decreasing and production in France and the United Kingdom increasing. In the former Soviet Union, production declined by about 9% compared with 1999 production. North America showed about a 4% increase, primarily from a production increase in Canada. Israel and Jordan, combined, reported an increase of less than 2% from that of 1999.

Canada.—Canpotex Ltd. reported an agreement with JSC Uralkali to form a joint marketing arrangement primarily in the Asian Pacific market but not in North America or Europe. (Fertilizer Markets, 2001; Potash Corp. of Saskatchewan, 2000; 2001a). Canpotex Ltd. sells offshore for the Saskatchewan operations of the three Canadian potash producers.

Chile.—In early 2000, Atacama Minerals Corp. decided to stockpile potassium nitrate ore while producing iodine. Potassium nitrate production was delayed for 6 years. Atacama Minerals estimated that world potassium nitrate consumption in 2000 was 450,000 metric tons per year (t/yr) with another 180,000 t/yr capacity starting up in Chile in the next 5 years (North American Minerals News, 2000a). Late in the year, another potassium nitrate producer, Compania de Salitre y Yodo, which already had a mine and mill at Pozo Almonte in northern Chile, announced a November startup of 90,000 t/yr capacity, using Canadian and Russian MOP as feedstock (Fertilizer Week, 2000a). The company mentioned plans for future iodine production.

China.—The Qarhan Lake potash project in Qaidam Basin of the Qinghai Province had been a joint venture between unnamed Chinese companies with Israel's Dead Sea Works Ltd. (DSW) and United Development Industries Co. (UDI) since 1993. They attempted to raise money as the Chinese Israeli Potash Co. (Cipco) in 1994 (European Chemical News, 1994). In 1998, the fundraising effort was the joint venture of Mingda Chemical Mines Co., DSW, and UDI (Fertilizer Week, 2000c) or Minda Chemical Corp. (Industrial Minerals, 2000b). In 2000, China seems to have taken control over the development at this site with a MOP project with reduced capacity of 180,000 t/yr under the name Qinghai Salt Lake Industry Group (Fertilizer Week, 2000b). Simultaneously, the Chaerhan Salt Lake Group has apparently commenced development of a MOP lake brine project near the city of Golmud in Qaidam Basin (Fertilizer Week, 2000c). Another joint venture, with the name of Lop Nor Sylvite Co., Ltd., in the Xinjiang Uyghar Autonomous Region, west of Qinghai Province, announced that it was working to develop MOP as an intermediate for producing SOP and potassium nitrate from the Lop Nor interior basin. The partners for this group are Sanwei Mining Co., the Xinjiang Delong Group Co., the Xinjiang Hami Gold Mine, and Xinjiang Nonferrous Metals Industrial Co., a regional government arm (Green Markets, 2000f).

Israel.—Haifa Chemicals Ltd. announced in May a 50% reduction in production to 67,500 t/yr of KNO_3 at the Haifa plant owing to world market conditions (Green Markets, 2000c). Haifa Chemicals reportedly has about 65% of world capacity and is owned by the U.S. company Trans-Resources, Inc. Haifa Chemicals opened talks with Israel Chemicals Ltd. for possible methods of cooperation (Green Markets, 2000b). There was a conflict between tourism and mineral sales at Eilat Port where dust from loading ships reached the hotels in the city. The Government of Israel operates the ports and has not invested in dust-free shiploading equipment, so it sought to shut down loading during tourist season. MOP would leave through this port towards the Asian markets (Green Markets, 2000a). DSW announced plans to increase MOP production by 0.36 Mt to 2.76 Mt (Green Markets, 2000g).

Russia.—JSC Uralkali Ltd., which operates the Berezniki plants in the Perm region, shipped some product through Fedcominvest in the early part of the year and through International Potash Co. in the latter part of the year, then sought a partnership with Canpotex International, Ltd., for 2001. JSC Uralkali had also started on the construction of a potash dock at the JSC St. Petersburg seaport, which is served by broad gauge rail, to replace the insufficient storage space at the port of Ventspils and to avoid the change of track gauge to standard gauge. JSC Uralkali had also chosen the Finnish port of Kotka, which is also served by broad gauge railroad tracks from mine to dock and is deep enough to handle panamax ships (Fertilizer Markets, 2001).

Spain.—Iberpotash S.A., which is the new name of the former Grupo Potasas, became majority-owned by DSW as of 1998 and is now 100% owned by DSW (Dead Sea Works Ltd., [undated], Iberpotash S.A.—Spain, accessed July 24, 2001, at URL http://www.dsw.co.il/iberp.htm). DSW announced plans to increase Spanish MOP capacity by about 12.5% or by 90,000 t/yr to 810,000 t/yr, but no timetable was given (Green Markets, 2000). Comercial de Potasas, S.A., the sales arm of Iberpotash, agreed to handle DSW potash sales into France, Portugal, and Spain (Industrial Minerals, 2000a). DSW has traditionally sold into those three countries because it ships from Ashdod on the eastern end of the Mediterranean Sea and sails past the French, Portuguese, and Spanish ports on the way to ports in the United States and Latin America.

Outlook

In the short to intermediate term, domestic potash consumption is likely to continue to vary within a 21-year historical band with a mean of 5.5 million metric tons per year (Mt/yr). That has been a band between 4.5 and 6.45 Mt/yr. There may be a slight downward trend as less potash will probably be needed for the same harvested areas owing to less weed competition in the fields for some crops. U.S. production is expected to remain relatively steady, and imports of potash will dominate the total supply. Demand should vary with U.S. food consumption and exports of U.S. farm crops and domestically fed meat products. Variations in demand come from combinations of weather pattern changes, national or regional (multinational) economy variations, and political decisions. On the world supply side, the world's largest potash producers are expected to continue to withhold some capacity from the world market for another year. The short- to intermediate-term outlook for world wide potash consumption is that more potash should be consumed in Asian and Latin American countries to balance out the fertilizer application rates and produce more crops per acre; European consumption might decline. The Government of Russia, or international organizations, will probably help Russian farmers purchase fertilizers to increase productivity per hectare so that Russia could become self-sustaining in food production. Some African nations will need international help to purchase potash-bearing fertilizers to achieve higher crop productivity. Over the long term, worldwide, more potash will be needed to feed a growing population.

PUMICE AND PUMICITE

By Wallace P. Bolen

Domestic survey data and tables were prepared by Virginia C. Harper, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

In 2000, pumice and pumicite consumption in the United States was 1.06 million metric tons (Mt). This consumption was about 9% greater than that of 1999 and represents the highest level of pumice consumption since 1979, when 1.12 Mt was consumed. The increase in consumption was attributable to greater domestic sales and increased imports of pumice and pumicite primarily for formed lightweight concrete products. Domestic production increased by about 8%, and exports, while still small relative to total domestic consumption, increased by about 17% (table 1).

The main use for pumice was as an aggregate in lightweight building blocks and assorted building products. Other major applications for pumice and pumicite included abrasive, absorbent, concrete aggregate and admixture, filter aid, horticulture (including landscaping), and the stonewashing of denim.

Production

Pumice and pumicite sold or used by U.S. producers increased to 697,000 metric tons (t) valued at $16.9 million (table 1). Oregon remained the leading source of pumice and pumicite, followed, in descending order, by California, New Mexico, Idaho, Arizona, and Kansas. Domestic production data for pumice and pumicite were developed by the U.S. Geological Survey (USGS) from a voluntary survey of U.S. operations. In 2000, 15 companies with 16 active operations produced and sold or used all the domestic pumice and pumicite in the United States. Because four of the companies did not respond to the 2000 survey, sold and used data for these companies were estimated. The 11 companies that responded represented about 81% of the 697,000 t.

Domestic producers, listed alphabetically by State, were Tufflite Inc., Phoenix, AZ; California Industrial Minerals Co., Friant, CA; California Lightweight Pumice, Inc., San Clemente, CA; Glass Mountain Pumice Inc., Tulelake, CA; U.S. Pumice Co., Chatsworth, CA; Amcor Precast, Inc., and Producers Pumice, Idaho Falls, ID; Hess Pumice Products, Inc., Malad City, ID; Calvert Corp., Norton, KS; Kansas Minerals Inc., Mankato, KS; Copar Pumice Co, Inc., Espanola, NM; CR Minerals Corp., Santa Fe, NM; Utility Block Co., Albuquerque, NM; Cascade Pumice Co., Bend, OR; and Sierra Cascade LLC, Chemult, OR.

Consumption

The amount of pumice and pumicite sold or used by U.S. producers rose in 2000 because of increased demand exclusively from the building block and concrete markets (table 2). Demand declined for all other uses except horticultural (including landscaping) applications, which remained at 1999 levels. The amount of pumice sold for building block increased by about 20%, to 470,000 t from 391,000 t. Sales of pumice and pumicite for abrasives, laundries (stonewashing), and miscellaneous markets decreased in 2000 compared with those of 1999. Sales of domestic stonewashing (or laundry) grade pumice continued to decrease following a trend that began in 1997. Sales fell to 6,000 t in

Pumice and Pumicite in the 20th Century

The production of pumice and pumicite in the United States, which started in 1897 with the shipment of 143 metric tons from mines in Nebraska and South Dakota and had increased to more than 544 tons in 1898, had practically ceased by 1900. Because of the distance of these deposits from the railroad and from large markets, domestic producers were not able to compete with pumice imported from Italy. Italian pumice was brought in as ballast in ships and therefore was inexpensively shipped. Italian pumice sold in New York for 4.4 to 6.25 cents per kilogram. About 80% of the domestic demand for pumice was supplied from Lapari, a small island north of Sicily. The Bureau of Statistics of the Department of Treasury kept no record of the amount of pumice imported but the data the Bureau of Statistics kept on the value of pumice imported listed the annual value of imports between $43,000 and $65,000 for the period between 1893 and 1899. Pumice was crushed and bolted for drying and used in the manufacture of various polishing powders and scouring stones.

By 2000, 385,000 tons of pumice and pumicite valued at about $14 million was imported, mostly from Greece. The main use for pumice in 2000 was as a lightweight aggregate in variously shaped and sized concrete building and decorative blocks. Pumicite was mostly used in filtration and in abrasives. Abrasive uses consumed only a small percentage of the pumice and pumicite. Pumice mining in the United States was concentrated in California, Idaho, New Mexico, and Oregon; 16 mines in the Western United States produced and sold or used nearly 700,000 tons. Domestic producers continued to suffer a transportation disadvantage when trying to ship to the Eastern United States, making it possible for imports to supply many of the markets from the Great Lakes region to the Gulf Coast.

Digitized by Google

2000 from 16,000 t in 1999, which represents a decrease of about 63%.

The most important market for pumice remained building block, which consumed 67.4% of the total pumice sold or used in the United States. Other important uses were horticulture and landscaping (14.3%), concrete aggregate (6.6%), and abrasives (3.7%). The remaining pumice and pumicite (8%) was used as absorbent (including pet litter), diluents, fill, filter aids, in laundries, in pottery clays, and for other unspecified uses.

Prices

The average prices reported for pumice and pumicite varied greatly by use compared with the average price for all uses in 2000. The overall average price was $24.27 per metric ton in 2000, a decrease of $3.42 from $27.69 per ton in 1999. The price change was primarily the result of a decrease in the average price reported for the grades of pumice used in building block. This decrease in price more than offset increases in the average prices for abrasives, concrete aggregate, and miscellaneous uses. Average prices per ton for pumice and pumicite by use, in descending order, were $215 for abrasive, $110 for stone washing, $38 for concrete admixture and aggregate, $29 for horticulture/landscaping, $20 for miscellaneous uses, and $11 for building block.

Foreign Trade

Exports of pumice increased to 27,000 t with a value of $15.3 million. Importing countries were led by Canada (29%), Japan (18%), Germany (9%), Malaysia (8%), Mexico (7%), Brazil (5%), and the United Kingdom (5%). The remaining 19% of exports went to 32 other countries in Asia, Central America, Europe, the Middle East, Oceania, and South America.

By volume, most imports of pumice and pumicite were for construction-related uses with smaller amounts used for abrasives and stonewashing. Greece remained the largest source of pumice imports, supplying more than 79% (table 3). In 2000, imports increased by about 8% to 385,000 t compared with that of 1999. Imports from Greece increased by 6% to 305,000 t, while imports from Italy nearly doubled to about 60,000 t compared with those of 1999. Imports from Mexico and Turkey were about the same as in 1999. In addition to these countries, 12 other countries exported pumice and pumicite to the United States in 2000.

World Review

The USGS estimated world pumice (and related materials) production at 12 Mt in 2000, about the same as in 1999 (table 4). Most of the data published were provided by official government agencies in each country. Large revisions of data are reported by these agencies usually without supporting explanations. Globally, Italy remained the dominant producer of pumice and pozzolan, with production estimated to be 4.6 million metric tons per year. Other leading countries in the production of pumice and related materials were Chile, Ecuador, Ethiopia, France, Germany, Greece, Spain, Turkey, and the United States. In addition, at least 16 other countries produced pumice.

Pumice is used more extensively outside of the United States, which helps to explain the large global production and sales of pumice relative to the United States. In Europe, for example, basic home construction uses significantly less gypsum sheetrock, stone and concrete being usually the preferred building materials. Prefabricated lightweight concrete walls are often produced and shipped to construction locations. Because of its lightweight, strength, and cementitious properties, pumice performs very well in the European style of construction.

Outlook

Consumption of pumice and pumicite in 2001 should stay at about 2000 levels, because construction activity is expected to slow down with the cooling economy. Imports and exports are expected to increase slightly from 2000 levels in 2001.

RARE EARTHS

By James B. Hedrick

Domestic survey data and tables were prepared by Heather A. Geissler, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Rare earths were first produced commercially in the 1880s with the mining in Sweden and Norway of the rare-earth thorium-phosphate mineral monazite. Production in Scandinavia was prompted by the invention in 1884 of the Welsbach incandescent lamp mantle, which initially required the oxides of zirconium, lanthanum, and yttrium, with later improvements requiring only the oxides of thorium and cerium. The mantles also used small amounts of neodymium and praseodymium as an indelible brand name label. The first rare-earth production in the United States was recorded in 1893 in North Carolina; however, a small tonnage of monazite was reportedly mined as early as 1887. South Carolina began production of monazite in 1903. Foreign production of monazite occurred in Brazil as early as 1887, and India began recovery of the ore in 1911. In 2000, rare-earth production was primarily from China, with lesser amounts in Brazil, India, Russia, and the United States.

The principal economic rare-earth ores are lateritic ion-adsorption clays and the minerals bastnäsite, loparite, and monazite (table 2). The rare earths are a moderately abundant group of 17 elements composed of scandium, yttrium, and the 15 lanthanides. The elements range in crustal abundance from cerium, the 25th most abundant element of the 78 common elements in the Earth's crust at 60 parts per million (ppm), to thulium and lutetium, the least abundant rare-earth elements at about 0.5 ppm. In rock-forming minerals, rare earths typically occur in compounds as trivalent cations in carbonates, oxides, phosphates, and silicates.

Scandium, whose atomic number is 21, is the lightest rare-earth element. It is the 31st most abundant element in the Earth's crust, with an average crustal abundance of 22 ppm. Scandium is a soft, lightweight, silvery-white metal, similar in appearance and weight to aluminum. It is represented by the chemical symbol Sc and has one naturally occurring isotope. Although its occurrence in crustal rocks is greater than lead, mercury, and the precious metals, scandium rarely occurs in concentrated quantities because it does not selectively combine with the common ore-forming anions.

Yttrium, whose atomic number is 39, is chemically similar to the lanthanides and often occurs in the same minerals as a result of its similar ionic radius. It is represented by the chemical symbol Y and has one naturally occurring isotope. Yttrium's average concentration in the Earth's crust is 33 ppm and is the second most abundant rare earth in the Earth's crust. Yttrium is a bright silvery metal that is soft and malleable, similar in density to titanium.

The lanthanides comprise a group of 15 elements with atomic numbers 57 through 71 that include the following: lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), promethium (Pm), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), and lutetium (Lu). Cerium, which is more abundant than copper (whose average concentration in the Earth's crust is 50 ppm), is the most abundant member of the group at 60 ppm, followed, in decreasing order, by yttrium at 33 ppm, lanthanum at 30 ppm,

Rare Earths in the 20th Century

In 1900, rare earths were produced to supply materials for lighting applications. Cerium was recovered as a byproduct of processing the rare-earth thorium-phosphate mineral monazite for its thorium content. A small amount of cerium (1%) was added to thorium to create the mixture used to produce an incandescent lamp mantle. When heated, the oxides of thorium and cerium glowed a brilliant white and allowed homes, businesses, and factories a low-cost way to illuminate the evening hours. U.S. monazite production in 1900 was mainly from North Carolina, with a smaller amount from South Carolina, amounting to 412 metric tons valued at $48,805. Rare earths also were mined for yttrium at the start of the 20th century. The yttrium-bearing minerals gadolinite and fergusonite and lesser amounts of cyrtolite (zircon variety) were mined at Barringer Hill, TX, for use in the Nernst lamp. The incandescent lamp mantle industry was established in 1884 with mantles of zirconium, lanthanum, and yttrium oxides. By 1900, the zirconium oxide mantle mixture had been replaced with an improved, brighter oxide mixture of thorium and cerium. That same year, the Nernst lamp came into use and used rods or "glowers" made of 25% yttrium oxide and 75% zirconium oxide, essentially an yttria stabilized zirconia. In this lamp, it was necessary to heat the glowers with an auxiliary device to about 700° C, at which point it became conductive and glowed with a brilliant white incandescence caused by the ceramic's resistance. With the advent of the electric incandescent lamp around 1912, yttrium oxide's use in Nernst glowers declined. The first large-scale use of rare-earth metals occurred in 1903 with the development of iron-bearing mischmetal (a natural mixture of rare-earth metals) in a pyrophoric cerium-rich alloy (ferrocerium) for lighter flints.

In 2000, rare earths were produced in the United States by only one mine at Mountain Pass, CA. The mine produced rare-earth concentrates from the ore mineral bastnäsite. China was the world's leading producer of rare earths, producing most of its rare earths from ores of bastnäsite, monazite, and ion adsorption clays. Over the past 100 years, the use of rare earths grew from hundreds of tons in 1900 to tens of thousands of tons in 2000. The principal applications in 2000 were in automotive catalytic converters; glass polishing and ceramics; permanent magnets; petroleum refining catalysts; metallurgical additives and alloys, including rechargeable batteries; and phosphors for color monitors, televisions, and energy-efficient fluorescent lighting.

Digitized by Google

and neodymium at 28 ppm. Thulium and lutetium, the least abundant of the lanthanides at 0.5 ppm, occur in the Earth's crust in higher concentrations than antimony, bismuth, cadmium, and thallium.

The rare earths were discovered in 1787 by Swedish Army Lieutenant Karl Axel Arrhenius when he collected the black mineral ytterbite (later renamed gadolinite) from a feldspar and quartz mine near the village of Ytterby, Sweden (Weeks and Leicester, 1968, p. 667). Because they have similar chemical structures, the rare-earth elements proved difficult to separate. It was not until 1794 that the first element, an impure yttrium oxide, was isolated from the mineral ytterbite by Finnish chemist Johann Gadolin (Weeks and Leicester, 1968, p. 671).

The elemental forms of rare earths are iron gray to silvery lustrous metals that are typically soft, malleable, ductile, and usually reactive, especially at elevated temperatures or when finely divided. Melting points range from 798° C for cerium to 1,663° C for lutetium. The unique properties of rare earths are used in a wide variety of applications.

In 2000, consumption was estimated to have increased as imports of individual rare-earth compounds increased. Production of bastnäsite continued in the United States as production of cerium concentrates resumed on a limited scale. As a result, imports of cerium compounds decreased (table 1). Since March 1998, refinery production at the Mountain Pass, CA, site of Molycorp, Inc., has been suspended because of low rare-earth prices on world markets and unresolved regulatory and permitting requirements for a wastewater system (Unocal Corp., 2000, p. 15).

Demand decreased for rare earths used in petroleum fluid cracking catalysts and in rare-earth phosphors for television, x-ray intensifying, and fluorescent and incandescent lighting. Yttrium was used primarily in lamp and cathode-ray tube phosphors, and lesser amounts were used in structural ceramics and oxygen sensors.

The domestic use of scandium increased in 2000, but overall consumption remained small. Commercial demand increased primarily as a result of increased demand for baseball and softball bats. Most scandium metal, alloys, and compounds were used in sporting goods equipment, metallurgical research, and analytical standards. Minor amounts were used in specialty lighting and semiconductors.

Production

In 2000, one mining operation in California accounted for all domestic mine production of rare earths. Molycorp, a wholly owned subsidiary of Unocal Corp., mined bastnäsite, a rare-earth fluorocarbonate mineral, by open pit methods at Mountain Pass, CA. Mine production was estimated to be 5,000 metric tons (t) of rare-earth oxide (REO) in concentrates.

Refined lanthanides were processed by two companies in 2000. Molycorp ceased production of refined compounds from bastnäsite at its separation plant at Mountain Pass in 1998. Unocal's higher environmental-related expenses in 2000 were in part related to the decontamination and decommissioning of Molycorp's Washington, PA, rare-earth metals site. Unocal also set aside $64 million for the future cost of the remediation of its operating oil and gas fields; this amount includes funds for Molycorp's Mountain Pass operation (Unocal Corp., 2001, p. 41-42).

Santuko Metal Industry Co., Ltd., of Japan was renamed Santoku Corp. in April 2000 (Santoku America, Inc., 2000, About us—Our history and our future, accessed July 18, 2001, at URL http://www.santoku.com/About%20Us.htm). Its U.S. subsidiary, Santoku America, Inc., produced rare-earth magnet and rechargeable battery alloys at its operations in Tolleson, AZ. Santoku America produced both major types of high strength permanent magnets, namely neodymium-iron-boron and samarium-cobalt. For the rechargeable battery industry, Santoku produced nickel-metal hydride (Ni-MH) alloys incorporating specialty rare-earth mischmetals. The plant also produced a full range of rare-earth metals in cast and distilled forms.

Rhodia Rare Earths Inc. announced it would change its name effective January 1, 2001, to Rhodia Electronics and Catalysis, Inc. The new name reflects Rhodia's mission to be a development partner and supplier of rare earths and advanced materials for the electronics and catalysis markets worldwide (Rhodia Rare Earths, Inc., December 18, 2000, La lettre du president, accessed July 17, 2001, at URL http://www.rhodia.ext.imaginet.fr/fr/index.htm).

Rhodia's operations produced finished rare-earth products from imported materials at its plant in Freeport, TX. Rhodia continued to operate its large-scale rare-earth separation plant in La Rochelle, France, and had additional capacity at its joint-venture Anan Kasei, Ltd. (Rhodia Rare Earths, 67%, and Santoku Metal Industry Co., Ltd., 33%) in Kobe, Japan. These plants provide Rhodia's U.S. operations with most of their supply.

Grace Davison, a division of W.R. Grace & Co., refined rare earths from rare-earth chlorides and other rare-earth compounds for petroleum fluid cracking catalysts at Chattanooga, TN. Grace Davison also produced rare-earth compounds for chemical catalysis and polishing compounds.

Essentially all purified yttrium was derived from imported compounds. The minor amounts of yttrium contained in bastnäsite from Mountain Pass, CA, are not recovered as a separate product.

Three scandium processors operated in 2000. High-purity products were available in various grades, with scandium oxide produced at up to 99.999% purity. Sausville Chemical Co. refined scandium at its facilities in Knoxville, TN. The company expected to produce high-purity scandium compounds, including oxide, fluoride, nitrate, chloride, and acetate. Boulder Scientific Co. processed scandium at its Mead, CO, operations. It refined scandium primarily from imported oxides to produce high-purity scandium compounds, including diboride, carbide, chloride, fluoride, hydride, nitride, oxalate, and tungstate.

Scandium also was purified and processed from imported oxides at Aldrich-APL in Urbana, IL, to produce high-purity scandium compounds, including oxide, fluoride, iodide, and hydrous and anhydrous chloride. The company also produced high-purity scandium metal.

Principal domestic producers of neodymium-iron-boron magnet alloys were Magnequench International, Inc., Anderson, IN; and Santuko America, Inc. (previously Rhodia, Inc.), Tolleson, AZ. Leading U.S. producers of rare-earth magnets were Crumax Magnetics, Inc., Elizabethtown, KY; Electron Energy Corp., Landisville, PA; Magnaquench UG (previously Ugimag, Inc.), Valparaiso, IN; Magnequench, Inc. (MQ), Anderson, IN; and the Magnetic Materials Division of Hitachi Metal America, Ltd., Edmore, MI, and China Grove, NC.

World production of neodymium-iron-boron magnets in 1999, for which the latest data are available, was 13,500 t for sintered magnets and 2,740 t for bonded magnets (Roskill's Letter from Japan, 2001c). Since 1990, the growth rates for magnets have been 28.6% per year for the sintered and 25.7% for the bonded. Similar growth in demand occurred over the past decade (1990-1999) for the principal rare-earth magnet component neodymium and the alloying additive dysprosium.

Digitized by Google

In the last quarter of 1999, Moltech Corp. announced it had acquired Energizer Power Systems from Eveready Battery Co., forming the new wholly owned subsidiary Moltech Power Systems. Moltech Power Systems produced Ni-MH rechargeable batteries (Rare-earth Information Center Insight, 2000a).

MQ of Anderson, IN, announced it had purchased two companies related to its rare-earth magnet business. First, MQ purchased Ugimag's sintered samarium-cobalt and neodymium-iron-boron (Nd-Fe-B) permanent magnet operations in Singapore, Switzerland, the United Kingdom, and the United States (Valpariso, IN), from the Carbone Lorraine Group in November (Magnaquench, Inc., 2000a). In the second aquisition, MQ purchased Widia Magnet Engineering from Milacron, Inc. The new company was renamed Magnaquench GmbH. It is a wholly owned subsidiary of MQ. Located in Essen, Germany, the plant produces injection molded bonded magnets (Magnaquench, Inc., 2000b).

Demand increased for rare earths used in Ni-MH batteries. The rechargeable batteries are used in cellular phones, notebook computers, personal data assistants (PDAs), camcorders, and other portable devices. Japan, the leading producer, shipped 1.021 billion units in 2000, a 19% increase compared with 1999 (Roskill's Letter from Japan, 2001a). Ni-MH batteries were the leading rechargeable battery product, followed distantly by nickel-cadmium and lithium-ion types.

TradeTech L.L.C. announced the sale of its newsletter and rare earths and specialty metals business to High Tech Materials of Longmont, CO. The company's electronic monthly newsletter Elements is available by e-mail subscription via URL http://www.RareEarthsMarketPlace.com.

Cerac, Inc., was purchased by its chief executive officer in conjunction with the private equity group Facilitator Capital Fund.

Etrema Products, Inc., a wholly owned subsidiary of Edge Technologies, Inc., of Ames, IA, and the sole supplier of the giant magnetostrictive alloy TERFENOL-D®, signed an agreement with Westport Innovations, Inc., of Canada to supply the alloy for use in diesel engines. Westport Innovations plans to use the "smart" material to control fuel flow in natural gas fuel injectors in light-duty diesel engines. Smart materials have the ability to adapt to outside influences, such as external magnetic fields. TERFENOL-D® is an alloy of iron and the rare-earth elements terbium and dysprosium that expands or contracts with the application or removal of an external magnetic field. It is used in actuators, acoustic devices, sonar, ultrasonics, and other smart materials for the oil and gas industry (Etrema Products, Inc., 2000a).

Consumption

Statistics on domestic rare-earth consumption were developed by surveying various processors and manufacturers, evaluating import-export data, and analyzing U.S. Government stockpile shipments. Domestic apparent consumption of rare earths increased in 2000 compared with that of 1999. Domestic consumption of rare-earth metals and alloys also increased in 2000, especially for those used in permanent magnets and rechargeable batteries.

Based on information supplied by U.S. rare-earth refiners and selected consumers and an analysis of import data, the approximate distribution of rare earths by use was as follows: automotive catalytic converters, 22%; glass polishing and ceramics, 39%; permanent magnets, 16%; petroleum refining catalysts, 12%; metallurgical additives and alloys, 9%; rare-earth phosphors for lighting, televisions, computer monitors, radar, and x-ray intensifying film, 1%; and miscellaneous, 1%.

In 2000, yttrium consumption was estimated to have increased to 454 t from 428 t in 1999. Yttrium compounds and metal were imported from several sources in 2000. Yttrium was imported from China (73.8%); Japan (21.9%); the United Kingdom (2.7%); Germany (1.3%); and France (0.3%). The estimated use of yttrium, based on imports, was primarily in lamp and cathode-ray tube phosphors (92.5%), structural ceramics and abrasives (5.2%), and alloys (2.3%).

Tariffs

In 2000, U.S. tariff rates specific to the rare earths, including scandium and yttrium, were unchanged from 1999 (U.S. International Trade Commission, 2000). Selected rare-earth tariff rates for countries with normal-trade-relations and non-normal-trade-relations status, respectively, were as follows: Harmonized Tariff Schedule of the United States (HTS) code 2805.30.0000 (rare-earth metals, including scandium and yttrium, whether intermixed or interalloyed), 5.0% ad valorem and 31.3% ad valorem; HTS code 2846.10.0000 (cerium compounds), 5.5% ad valorem and 35% ad valorem; HTS code 2846.90.2010 (mixtures of rare-earth oxides except cerium oxide), free and 25% ad valorem; HTS code 2846.90.2050 (mixtures of rare-earth chlorides), free and 25% ad valorem; HTS code 2846.90.4000 (yttrium-bearing materials and compounds containing by weight greater than 19% but less than 85% yttrium oxide equivalent), free and 25% ad valorem; HTS code 2846.90.8000 [individual rare-earth compounds, including oxides, nitrates, hydroxides, and chlorides (excludes cerium compounds, mixtures of REO, and mixtures of rare-earth chlorides)], 3.7% ad valorem and 25% ad valorem; HTS code 3606.90.3000 (ferrocerium and other pyrophoric alloys), 5.9% ad valorem and 56.7% ad valorem; HTS code 7202.99.5040 [ferroalloys, other (including rare-earth silicide)], 5.0% ad valorem and 25% ad valorem; and HTS code 7601.20.9090 [aluminum alloys, other (including scandium-aluminum alloys)], free and 10.5% ad valorem.

Special rare-earth tariffs for Canada and Mexico were the result of Presidential Proclamation 6641, implementing the North American Free Trade Agreement, effective January 1, 1994. Under the agreement, tariff rates for most rare-earth products from Canada and Mexico were granted duty free status, and those that were scheduled for staged reductions have achieved duty free status. Tariff rates for most other foreign countries were negotiated under the Generalized Agreement on Tariffs and Trade Uruguay Round of Multilateral Trade Negotiations.

Stocks

All U.S. Government stocks of rare earths in the National Defense Stockpile (NDS) were shipped in 1998. Periodic assessments of the national defense material requirements may necessitate the inclusion of rare earths in the NDS at a future date.

Prices

Rare-earth prices increased in 2000. The following estimates of prices were based on trade data from various sources. All rare-earth prices remained nominal and subject to change without notice. The competitive pricing policies in effect in the industry caused most rare-earth products to be quoted on a daily

Digitized by Google

basis. The average price of imported rare-earth chloride was $1.38 per kilogram in 2000, a decrease from $2.09 per kilogram in 1999. In 2000, imported rare-earth metal prices averaged $11.52 per kilogram, a decrease from $12.44 per kilogram in 1999. Mischmetal and specialty mischmetals comprised most rare-earth metal imports. (Mischmetal is a natural mixture of rare-earth metals typically produced by metallothermic reduction of a mixed rare-earth chloride.) The price range of basic mischmetal was from $5.00 to $7.00 per kilogram (in metric ton quantities) at yearend 2000, unchanged from the yearend 1999 price range (Elements, 2000). The average price for imported cerium compounds, excluding cerium chloride, increased to $4.57 per kilogram in 2000 from $4.43 per kilogram in 1999. The primary cerium compound imported was cerium carbonate.

The estimated market price for bastnäsite concentrate was $5.51 per kilogram ($2.50 per pound). The price of monazite concentrate, typically sold with a minimum 55% rare-earth oxide content, including thorium oxide, free on board (f.o.b.) as quoted in U.S. dollars and based on the last U.S. import data, was unchanged at $400.00 per metric ton. In 2000, no monazite was imported into the United States. Prices for monazite remained depressed because the principal international rare-earth processors continued to process only thorium-free feed materials.

The nominal price for basic Nd-Fe-B alloy, calculated from data supplied by several U.S. producers, was $15.50 per kilogram ($7.03 per pound), f.o.b. shipping point, 2,000-pound minimum. Most alloy was sold with additions of cobalt (typically 4% to 6%) or dysprosium (no more than 4%). The cost of the additions was based on pricing before shipping and alloying fees; with the average cobalt price decreasing to $33.42 per kilogram ($15.16 per pound) in 1999, the cost would be about $0.33 per kilogram ($0.15 per pound) for each percent addition.

Rhodia quoted rare-earth prices, per kilogram, net 30 days, f.o.b. New Brunswick, NJ, or duty paid at point of entry, in effect at yearend 2000, are listed in table 3. No published prices for scandium oxide in kilogram quantities were available. Yearend 2000 nominal prices for scandium oxide were compiled from information provided by several domestic suppliers and processors. Prices decreased from those of the previous year for most grades and were listed as follows: 99% purity, $700 per kilogram; 99.9% purity, $2,000 per kilogram; 99.99% purity, $3,000 per kilogram; and 99.999% purity, $6,000 per kilogram.

Scandium metal prices for 2000 were unchanged from those of 1999 (Alfa Aesar, 1999, p. 1023-1024) and were as follows: 99.99% REO purity lump, sublimed dendritic, ampouled under argon, $175 per gram; 99.9% REO purity less-than-250-micron powder, ampouled under argon, $395 per 2 grams; 99.9% purity lump, sublimed dendritic, ampouled under argon, $267 per 2 grams; and 99.9% REO purity foil, 0.025-millimeter (mm) thick, ampouled under argon, 25 mm by 25 mm, $98.80 per item.

Scandium compound prices as listed by Aldrich Chemical Co. (2000, p. 1476-1477) were as follows: scandium acetate hydrate 99.9% purity, $61.40 per gram; scandium chloride hydrate 99.99% purity, $53.80 per gram; scandium nitrate hydrate 99.9% purity, $63.30 per gram; and scandium sulfate pentahydrate 99.9% purity, $61.00 per gram. Prices for standard solutions for calibrating analytical equipment were $23.80 per 100 milliliters of scandium atomic absorption standard solution and $360.50 per 100 mm of scandium plasma standard solution.

Prices for kilogram quantities of scandium metal in ingot form have historically averaged about twice the cost of the oxide, and for higher purity distilled scandium metal have averaged about five times that cost.

Foreign Trade

U.S. exports of rare earths declined slightly and imports increased in 2000 compared with those of 1999. U.S. exports totaled 9,490,000 kilograms (kg) valued at $58.5 million, a slight decrease in quantity and an 8.5% increase in value compared with those of 1999 (table 4). Imports totaled 28,800,000 kg gross weight valued at $142 million, a 4.7% increase in quantity and a 1% decrease in value compared with those of 1999 (table 5).

In 2000, U.S. exports of rare earths were mixed with cerium compounds, which remained essentially unchanged; exports of rare-earth compounds and ferrocerium and pyrophoric alloys decreased; and exports of rare-earth metals increased. Principal destinations in 2000, in descending order, were Japan, Canada, the Republic of Korea, and Germany. The United States exported 1,370,000 kg of rare-earth metals valued at $9.6 million, a 2.6% increase in quantity compared with that of 1999. Principal destinations, in descending order of quantity, were Japan, the Republic of Korea, the United Kingdom, and Germany. Exports of cerium compounds, primarily for glass polishing and automotive catalytic converters, were essentially unchanged at 3,950,000 kg valued at $18.2 million. Major destinations, in descending order of quantity, were the Republic of Korea, Germany, Taiwan, and Mexico.

Exports of inorganic and organic rare-earth compounds decreased to 1,650,000 kg in 2000 from 1,690,000 kg in 1999, and the value of the shipments increased by 19% to $23.4 million. Shipments, in descending order of quantity, were to Taiwan, the Republic of Korea, China, and Canada.

U.S. exports of ferrocerium and other pyrophoric alloys decreased to 2,530,000 kg valued at $7.39 million in 2000 from 2,660,000 kg valued at $10.7 million in 1999. Principal destinations, in descending order of quantity, were Canada, the United Arab Emirates, Hong Kong, and Japan.

In 2000, U.S. imports of compounds and alloys increased for three out of seven categories, as listed in table 5. China and France dominated the import market, especially for mixed and individual rare-earth compounds, followed by Japan and India (figure 1).

Imports of cerium compounds totaled 6,450,000 kg valued at $29.4 million. After a decrease in imports in 1999, the quantity of cerium compounds imported increased by 8%, as a result of increased demand for automotive exhaust catalysts and despite the increased production from the major domestic producer. China was the major supplier for the sixth year in a row, followed by France, Japan, and Austria.

Imports of yttrium compounds containing between 19% and 85% of weight oxide equivalent (yttrium concentrate) decreased by 64% to 97,400 kg in 2000, and the value declined by 19% to $2.59 million. China was the leading supplier of yttrium compounds, followed by Japan, France, and Germany.

Imports of individual rare-earth compounds, traditionally the major share of rare-earth imports, increased by 45% compared with those of 1999. Rare-earth compound imports increased to 15,000,000 kg valued at $71.3 million. The major sources of individual rare-earth compounds were China, France, Estonia, and Japan. Imports of mixtures of rare-earth oxides, other than cerium oxide, decreased by 63% to 2,190,000 kg valued at $9.5 million. The principal source of the mixed rare-earth oxides was

Digitized by Google

China, with smaller quantities imported from the United Kingdom, Japan, and Germany. Imports of rare-earth metals and alloys into the United States totaled 2,060,000 kg valued at $23.7 million in 2000, a 39% increase in quantity compared with those of 1999. The principal rare-earth metal sources, in descending order of quantity, were China and Japan. Metal imports increased as demand for mischmetal for steel additives and specialty mischmetals for rechargeable batteries increased.

In 2000, imports of rare-earth chlorides decreased by 13% to 2,900,000 kg valued at $3.98 million. Supplies of rare-earth chloride, in descending order of quantity, came from China, India, the United Kingdom, and Japan. In the United States, rare-earth chloride was used mainly as feed material for manufacturing fluid cracking catalysts. Imports of ferrocerium and pyrophoric alloys decreased by 2.3% to 133,000 kg valued at $1.56 million. France was the principal supplier, with smaller amounts imported from Austria and Brazil.

World Review

China, France, India, and Japan were major import sources of rare-earth chlorides, nitrates, and other concentrates and compounds (table 5). Thorium-free intermediate compounds as refinery feed were still in demand as industrial consumers expressed concerns with the potential liabilities of radioactive thorium, the costs of complying with environmental monitoring and regulations, and costs at approved waste disposal sites. In 2000, demand for rare earths increased in the United States, and imports increased by 4.6%. Consumption in China increased at a similar rate at 4.3%, while Japanese imports increased substantially by 11.6%.

In 2000, estimated world production of rare earths increased slightly to 83,300 t of REO (table 6). Production of monazite concentrate production was estimated to be 6,200 t (table 7).

World reserves of rare earths were estimated by the U.S. Geological Survey to be 100 million metric tons (Mt) of contained REO in 2000. China, with 43%, had the largest share of those world reserves. Australia's reserves include rare earths contained in monazite owing to its widespread availability as a very low-cost byproduct of heavy-mineral sands processing.

Australia.—Australia remained one of the world's major potential sources of rare-earth elements from its heavy-mineral sands and rare-earth laterite deposits. Monazite is a constituent in essentially all of Australia's heavy-mineral sands deposits. It is normally recovered and separated during processing but in most cases is either returned to tailings because of a lack of demand or stored for future sale. In 2000, major producers of heavy-mineral sand concentrates, in order of potential production, in Australia were Iluka Resources, Ltd. (formerly RGC, Ltd., and Westralian Sands, Ltd.), Tiwest Joint Venture, Consolidated Rutile, Ltd. (CRL), and Cable Sands, Ltd.

Anaconda Nickel, Ltd., entered into an agreement with Ashton Mining, Ltd., and Lynas Corp., Ltd., to acquire all outstanding shares of the Mount Weld companies from Ashton. The Mount Weld deposit is a world-class rare earth carbonatite deposit with tantalum, niobium, and titanium content. After purchasing all issued shares of the three subsidiaries, Anaconda agreed to pay A$3.2 million to Ashton on completion, to provide 50% of A$7.5 million when the deposit is developed, and to receive from Lynas A$3.2 million from the sale of Mount Weld Rare Earths Pty., Ltd. Lynas will contribute 50% of the A$7.5 million and has appointed Anaconda to complete the final feasibility studies. A royalty, limited to $A10.7 million is to be shared equally between Mount Weld Rare Earths Project and the Mount Weld Metals Project payable after all project and financing costs are paid and based on a rate of 1% per year of revenues (Anaconda Nickel, Ltd., November 21, 2000, Anaconda reaches agreement with Ashton and Mount Weld, accessed August 27, 2001, at URL http://new.anaconda.com.au/company_releases/0011/2211.pdf).

Iluka was one of the world's largest producers of heavy-mineral sands in 2000 (Iluka Resources, Ltd., 2001, p. 9). The company operated eight mines in Australia and two in the United States. Iluka's Australian subsidiary, WA Titanium Minerals, operated six mines in Western Australia, two of which opened in 2000. The company commissioned the Capel North West Mine in January near Capel. In October, WA Titanium brought online its second operation, the North Mine and Newman concentrator near Eneabba. Other mining operations were the South Mine near Eneabba and the Yoganup, the Yoganup Extended, and the Busselton mines in the southwestern region. Iluka's two east coast mines, in which it had a 43% interest, were operated by CRL on North Stradbroke Island, New South Wales.

Iluka upgraded the ore grade at its Ouyen deposit in northwestern Victoria by 28%. The inferred resource at Ouyen was increased by 1.7 Mt to 7.7 Mt grading 11.4% heavy minerals, containing 40% ilmenite, 15% rutile, and 9% zircon (Iluka Resources, Ltd., 2000, p. 3-4).

Iluka calculated resources for two of its heavy-mineral sands deposits in the Perth Basin of Western Australia. The Red Gully deposit to the north and the Dandalup deposit to the south of Perth displayed resources of 942,000 t of heavy minerals (Iluka Resources, Ltd., 2000).

Australian Zirconia, Ltd., a wholly owned subsidiary of Alkane Exploration, Ltd., announced it had produced a 99.3% zirconium oxide and hafnium oxide product from its Dubbo hard-rock rare-earth-and-zirconium-bearing deposit in New South Wales. DEMA Pty., Ltd., was the feasibility study manager and consultant for the project. The multimineral deposit is located on the Toongi alkaline intrusive that contains hafnium, lanthanides, niobium, tantalum, yttrium, and zirconium in the igneous rock trachyte. Based on a planned 200,000-metric-ton-per-year (t/yr) sulfuric acid leach process, the plant was expected to produce 3,500 t/yr zirconium oxide (and hafnium oxide), 500 t/yr to 1,500 t/yr of yttrium-lanthanide concentrate, and 900 t/yr of tantalum-niobium pentoxide concentrate (Australian Zirconia, Ltd., December 2000, Dubbo zirconia project, accessed May 8, 2001, at URL http://www.alkane.com.au/zirconia.html).

Basin Minerals, Ltd., announced the completion of a prefeasibility study of its Douglas heavy-mineral sands deposit in the Murray Basin in western Victoria. The Douglas deposit covers an area of 5,860 square kilometers and has a resource of 22.4 Mt of heavy minerals. The area contains the Acapulco, Bondi, Bondi East, and Echo strandline deposits containing 11.3 Mt of ilmenite (including leucoxene), 1.26 Mt of rutile, and 1.62 Mt of zircon. The project had an anticipated projected startup date of 2003 (Basin Minerals, [undated], Mineral sands exploration overview—Douglas project, accessed May 2, 2001, at URL http://www.basinminerals.com.au/projects.html).

Basin Minerals explored five heavy-mineral sands deposits in the Murray Basin area of South Australia, Victoria, and New South Wales. The principal deposits were the Douglas project in Victoria, the Culgoa project in northern Victoria, the Baranald-Swan Hill in New South Wales and Victoria, the Oakville in northern South Australia, and the Pooncarie in western New South Wales. Total resources of the Douglas and the Culgoa deposits were 24.4 Mt of heavy-mineral concentrates contained in 393 Mt of ore grading 6.2% heavy minerals,

Digitized by Google

including monazite (Basin Minerals, [undated], Mineral sands exploration overview—Table 1, accessed May 2, 2001, at URL http://www.basinminerals.com.au/projects.html).

Basin Minerals acquired additional land adjacent to its Douglas deposit in Victoria. The State of Victoria awarded successful bids to Basin Minerals for block 2 in the Murray Basin which includes the former CRL WIM 100 deposit with 860 Mt of ore grading 5.9% heavy minerals (Mineral Sands Report, 2000b).

BeMaX Resouces NL announced the results of its pilot plant at its Ginkgo Mineral Sands Joint Venture (MSJV). The MSJV partners were BeMaX (50%), Imperial Mining (Aust) NL (25%), and Probo Mining Pty. Ltd. (25%). Located 120 kilometers (km) north of Mildura, Victoria, the Ginkgo deposit has an inferred resource of 260 Mt grading 2.6% heavy minerals. Initial tests showed product suitable for market including ilmenite, rutile, leucoxene, and zircon (BeMaX Resources NL, April 3, 2000, Update—Ginkgo mineral sands deposit, accessed March, 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

BeMaX purchased Imperial Mining's 25% share of MSJV, raising BeMaX's holdings to 75%. Imperial Mining was a wholly owned subsidiary of Imperial One, Ltd. (BeMaX Resources NL, October 10, 2000, Completion of purchase of Imperial Mining (Aust) NL, accessed March 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

BeMaX released information on a heavy-mineral strandline discovery that straddles BeMaX's BIP Joint Venture property and the property of Iluka Resouces in the Murray Basin. The adjacent Snapper (BeMaX) and Trelega (Iluka) deposits straddle the mining exploration claims at the southwest edge of BIP Joint Venture's EL5474 property in Victoria (BeMaX Resources NL, October 10, 2000, Mineral Sands discovery straddles boundary of BeMaX's and Iluka's Properties, accessed March 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

Mineral Deposits, Ltd. (MDL), stated that it would restart its Viney Creek dredge mine in New South Wales in 2001 because of increased demand for heavy minerals and a weak Australian dollar against the U.S. dollar. The 2,500-ton-per-hour dredge was placed on standby in April 1999 because of weak demand for rutile and zircon. The dredge will be refurbished in the last quarter of 2000. MDL's Hawks Nest dry mill continued to operate with feed from its smaller dredge operation at Fullerton, New South Wales (Mineral Sands Report, 2000c).

Tiwest Joint Venture, an Australian collaboration of U.S.-based Kerr McGee Chemical LLC's subsidiary KMCC Western Australia Pty., Ltd., and Australian-based Ticor Resources Pty., Ltd., produced heavy-mineral sands from its Cooljarloo Mine in Western Australia. In 2000, Tiwest processed 918,000 t of heavy-mineral concentrates compared with 548,498 t of heavy-mineral concentrates in 1999 (Mineral Sands Report, 2001c). The large increase in production was the result of the Cooljarloo Mine upgrade project in 2000. The capacity of heavy-mineral concentrates at Cooljarloo was increased to 675,000 t/yr from 535,000 t/yr, a 20% gain. Tiwest's expansion cost was A$20 million and was designed and implemented by contractor HBH Consultants (The Institution of Engineers, Australia, 2001, Australian Engineering Excellence Awards 2000—Cooljarloo Mine upgrade project for the Tiwest joint venture, accessed March 22, 2001, at URL http://www.ieaust.org.au/events/aeea_entrants/aeea_entrantdetails8.html).

RZM Pty., Ltd., purchased Western Metals, Ltd.'s 30% stake in the Wemen heavy-mineral sands project in the Murray Basin, Victoria, for A$5 million. Following the buyout, RZM entered into a 50-50 joint venture with the Australian company Sons of Gwalia for its Murray Basin mineral resource tenements and freehold land and a 50% share of RZM's heavy-mineral sands processing equipment and operations at Tomago, New South Wales. Production from the deposit is scheduled for 2001. Wemen is forecast to produce heavy-mineral sands over the 6 years of the mine's life (Industrial Minerals, 2000a).

Austria.—Treibacher Industrie AG announced it was being purchased for more than $100 million by August Finck Group of Munich, Germany. Treibacher AUERMET Produktionsges m.b.H, the rare-earth subsidiary of Treibacher Industrie AG, is expected to continue its planned expansion. Treibacher's capacity was 8,000 t/yr of rare-earth products and alloys and produced lighter flints, mischmetal, hydrogen storage alloys for batteries, vacuum alloys, mixed rare-earth compounds for fluid cracking catalysts, ceramic materials, additives for glass and ceramics, and specialty pure metals and alloys (Rare-earth Information Center News, 2000a).

Brazil.—Reserves of monazite contained in marine alluvial deposits were 42,000 t, and in stream placers, 40,000 t in 1999, the latest available data. The reserves of marine origin were distributed in deposits primarily in the States of Rio de Janeiro (26,730 t), Bahia (10,186 t), and Espírito Santo (4,136 t). The main placer reserves were in the States of Minas Gerais (24,396 t), Espírito Santo (11,372 t), and Bahia (3,481 t) (Fabricio da Silva, 2000, p. 107-108).

China.—Production of rare-earth concentrates in China was 70,000 t REO in 1999, the latest available data. Refined and processed products reached 60,000 t REO. Production of individual high-purity rare-earth compounds and metals was 25,000 t REO, an increase of 66% from those of 1998. Consumption within China increased by 4.3% in 1999 to about 16,000 t REO. Metallurgical applications, the major domestic use, consumed 5,200 t of equivalent REO (China Rare Earth Information, 2000a).

In 1999, China produced 160 million Ni-MH batteries containing 500 t of rare-earth metals. Rare-earth-containing steel consumed 400 t of rare earths as an alloying agent in 700,000 t of steel. Cast iron, a traditional application of rare-earth metals, consumed 3,800 t in making 1.1 Mt of metal in 1999. Nonferrous alloys, including aluminum wire and cable, used 800 t of rare earths, primarily for grain refinement and improved conduction. Consumption of rare earths by the oil industry was 3,800 t in fluid-cracking catalysts (China Online, [April 2000], China's consumption rare earth to rise 10%/yr, accessed October 11, 2000, at URL http://www.chinaonline.com/industry/metal_mining/NewsArchive/Secure/april/B200032214a.asp).

Inner Mongolian Rare Earth Group, Inc. (IMREG), was established in Baotou, Inner Mongolia, in November 1999 to address the status of the industry. Its primary goals were to integrate rare-earth research and development, production, and trade; to provide quality products; and to monitor the rare-earth industry of the region. The state-owned entity will also control the rate of rare-earth concentrate production and adjust the product structure to the market. IMREG expects to strengthen the development of the downstream processes and products and plans to improve international cooperation (China Rare Earth Information, 2000c).

Sichuan Panxi Rare Earth, Ltd., was declared bankrupt in May 2000. The company had capacity to process 2,000 t/yr of bastnäsite concentrate. Sichuan Panxi operated from May 1996 until January 1998 in Xi-xiang Village, Xichang City, in Sichuan Province (China Rare Earth Information, 2000b). The availability of rare earths from China continues to be strong,

Digitized by Google

especially from Inner Mongolia. The rare-earth content of the iron ore mined at Baiyun Obo, Inner Mongolia, ranges from 400,000 t/yr to 500,000 t/yr REO (China Rare Earth Information, 2000d). Only a portion of this material is processed annually to recover rare earths.

Rhodia Rare Earths announced the formation of a joint venture with Beijing Founder Group Co., Ltd., and Liyang Licheng Economic General Industrial Co., Ltd., to group the holdings of the Liyang rare-earth plant and to develop new manufacturing units using Rhodia's expertise. Located in Jiangsu Province near Shanghai, the joint venture will be called Liyang Rhodia Founder Rare Earth New Material Co., Ltd. Rhodia Rare Earths will have a 45% share in the new company, which plans to develop products for the electronic, automotive, glass, and chemical markets (Rhodia Rare Earths, Inc., September 7, 2000, Rhodia develops its rare-earth activities in China, accessed July 17, 2001, at URL http://www.rhodia.ext.imaginet.fr/fr/index.htm).

France.—Rhodia of France and CTI, Inc., of the United States have signed an agreement to develop and supply rare-earth compounds used in medical imaging devices based on positron emission tomography (PET). Medical imaging with PET is based on recording the positron emissions from an intravenous tracer (Rhodia Rare Earths, Inc., June 21, 2000, Rhodia/CTI, Inc. agreement for the use of rare earths in state-of-the-art medical imaging, accessed July 18, 2001, at URL http://www.rhodia.ext.imaginet.fr/fr/index.htm). CTI manufactures whole-body 2D and 3D PET scanning devices that incorporate the rare-earth compound lutetium oxyorthosilicate (LSO) as a photon detector crystal. CTI grows LSO scintillation crystals and produces the PET detectors that incorporate the crystals (CTI, Inc., [2000], Detector systems, accessed July 19, 2001, at URL http://www.cti-pet.com/cti_detector.html).

India.—Exploration for heavy-mineral sands has increased. Australian-based MDL, and Iscor, Ltd., have formed an alliance to complete feasibility studies on three deposits in the State of Tamil Nadu at Kudiraimozhi, Sattankulam, and Navaladi (Mineral Sands Report, 2001b).

MDL and Iscor have signed a memorandum of understanding to form an alliance to develop two heavy-mineral sands deposits in Tamil Nadu State. The Tamil Nadu deposits at Kudiraimozhi and Navaladi-Sattankulam contain 1 billion metric tons of ore grading 6.2% ilmenite, 0.4% rutile, and 0.7% zircon (Mineral Deposits, Ltd., November 1, 2000, Announcements—Indian mineral sands project, accessed June 14, 2001, via URL http://www.mineraldeposits.com.au/Announcements2000.html).

Kerala Minerals and Metals, Ltd. (KMML), is planning an expansion of its operations at Chavara. KMML has reserves of 18 Mt grading up to 50% heavy minerals. The heavy minerals contain 65% to 75% ilmenite, 5% to 7% rutile, and 4% to 8% zircon (Titanium Minerals Outlook, 2000).

Japan.—Japan refined 5,625 t of rare earths in 2000 from imported ores and intermediate raw materials, an increase of 10% from that of 1999 (Roskill's Letter from Japan, 2001d). Imports of rare earths during the year were 26,928 t, an increase of 18% from those of 1999. The value of imports increased to ¥23,843 million in 2000 from ¥17,812 million in 1999. Japanese rare-earth imports of yttrium oxide, cerium oxide, lanthanum oxide, rare-earth metals, and cerium compounds (other than cerium oxide) increased. Imports of rare-earth compounds (including intermediate raw materials) and ferrocerium decreased. Imports from the United States were 530 t, a decrease from the 609 t imported in 1999.

China continued as the leading source of rare-earth imports for Japan with 22,431 t, representing 81% of the total. Imports from China in 2000 were as follows: rare-earth metals, 6,993 t; cerium compounds, 4,977 t; cerium oxide, 3,821 t; rare-earth compounds, 3,786 t; lanthanum oxide, 1,568 t; yttrium oxide, 1,181 t; rare-earth chlorides, 77 t; and ferrocerium, 28 t (Roskill's Letter from Japan, 2001b).

Kenya.—Tiomin Resources, Inc., of Toronto, Canada, raised Can$5 million through the private offering of warrants for investments in its Kwale heavy-mineral sands deposit. The money was expected to be used to acquire surface mining rights at its Kwale deposit and to finalize detailed engineering plans for the heavy-mineral sands mine (Mineral Sands Report, 2000e). The Kwale deposit is divided into three economic zones of Pliocene age: the North Dune, the Central Dune, and the South Dune. Monazite and other heavy minerals are contained in the Magarini Sands Formation. The magarini sands form a belt of low hills believed to be aeolian in origin. Resources of the Kwale deposit are 200 Mt of ore (Tiomin Resources, Inc., [undated], Kwale (rutile, ilmenite and zircon), accessed May 16, 2001, via URL http://www.tiomin.com/s/Properties.asp?PropertyInfoID=316&PropertyMapID=1034].

Based on the results of a feasibility study by LTA Process Engineering Pty., Ltd., of South Africa and Ausenco of Australia, Tiomin planned to start construction at Kwale in 2001. During its first 6 years, the mine is expected to produce 37,000 t/yr of zircon. Kwale has a mine life of 14 years (Industrial Minerals, 2000e).

Mozambique.—Kenmare Resources plc of Dublin, Ireland, bought the heavy-mineral sands dry separation plant from BHP, Ltd.'s Beenup Mine in Western Australia, which closed in 1999 after being in operation less than a year (Industrial Minerals, 2000d). The 650,000 t/yr plant was purchased for $4.7 million and was expected to be installed at the Moma Titanium Minerals Project in Mozambique (Kenmare Resources plc, 2000a).

Kenmare had previously purchased BHP's wet concentrator in January for $1.4 million (Industrial Minerals, 2000c). The acquisition of both plants from the Beenup Minsands Project is expected to save Kenmare in excess of $60 million in capital expenditures. The Moma Titanium Minerals Project is scheduled to begin production in late 2002 (Kenmare Resources plc, 2000b).

South Africa.—Iscor announced it would begin development of its Hillendale Mine in Kwazulu Natal Province in the second quarter of 2001. Full production capacity of the mine, expected to be reached in 2003, will be 550,000 t/yr ilmenite, 100,000 t/yr zircon, 40,000 t/yr rutile, and 10,000 t/yr leucoxene. Reserves at the Hillendale deposit are 73 Mt grading 5.6% valuable heavy minerals (excluding magnetite) (Iscor, Ltd., [undated], Heavy minerals—Hillendale, accessed April 22, 2001, via URL http://www.iscor.com/mainframe.asp?imgname=01). Construction of the Hillendale Mine and wet concentrator plant began in April at a cost of $137 million. Construction also began on a central mineral separation plant at Empangeni, 20 km from the mine site. The separation plant was expected to come on-stream in the third quarter (Industrial Minerals, 2000b).

Ticor, Ltd., announced in October that it began a review of Iscor's heavy-mineral sands deposits in South Africa. Ticor was interested in acquiring a 50% share of the project, which has reserves of 16 Mt of heavy minerals. The project consists of three deposits: the Hillendale, the Fairbreeze, and the Gravelotte. The Hillendale was scheduled to be the first mine developed. The mine life of the three deposits is at least 20 years (Mineral Sands Report, 2000d).

Namakwa Sands (Pty), Ltd., a wholly owned subsidiary of Anglo American plc, increased its heavy-mineral sands

Digitized by Google

production as a result of the completion of its phase two expansion. Construction of the project, which was funded at 1.2 billion rand in 1997, was completed in 1999. Heavy-mineral sands were produced from its mine at Brand-se-Baai. Heavy-mineral concentrates were produced from its dry mill at Koekenaap (Mineral Sands Report, 2001a). The phase two expansion increased ore capacity to 12 million metric tons per year (Mt/yr) from 4 Mt/yr. The mine life of the deposit is 35 years.

Richard Bay Minerals completed construction of a new heavy-mineral sands processing plant. Completed in October 1999, the plant is designated mining plant E (Joseph, 2001).

Current Research and Technology

Rare-earth Ni-MH batteries are finding increased use in automobiles. The batteries are a powder alloy of mischmetal [nickel (Ni), cobalt (Co), manganese (Mn), and aluminum (Al)] pasted on a Ni-plated sheet. The principal alloy is produced by rapid solidification followed by a heat treatment and chemical of physical modification to increase the reactive Ni surface area. The Ni electrode is made of a spherical powder alloy of nickel-zinc-cobalt hydroxide (Ni, Zn, Co) $(OH)_2$ within a foamed Ni or Ni-fiber layer with a cobalt oxyhydroxide (CoOOH) coating. Ni-MH batteries are used in both hybrid electric vehicles (HEV) and pure electric vehicles (PEV). Commercially available HEVs in the United States in 2000 were the 1-liter, 3-cylinder-engine Honda Insight and the 1.5-liter, 4-cylinder-engine Toyota Prius. The Prius' Ni-MH battery produces 274 volts, and the Insight's outputs 144 volts. PEVs are produced internationally by Daihatsu, Honda, Mazda, Mitsubishi, Nissan, Subaru, Suzuki, and Toyota. Driving ranges of the PEVs vary from 55 km to 240 km (Rare-earth Information Center News, 2000b).

Yttria-stabilized zirconia (YSZ), a material extensively used as an oxygen sensor in automobile engines, has been adapted for use as a sulfur dioxide (SO_2) sensor. The sensor is a layered device with a silver-coated platinum grid, a layer of silver sulfate-based salt, a YSZ ceramic layer, and a platinum electrode. To detect SO_2, the compound must first be oxidized to SO_3 on the platinum grid. In the presence of SO_3, the O_2 is dissociated on the platinum reference electrode, and the O^{2+} is conducted through the YSZ. The reaction $2Ag + O^{2+} + SO_3 = Ag_2SO_4 + 2e^-$ occurs at the sensing electrode. This electron imbalance causes a linear electromagnetic field (EMF) to occur between the reference electrode and the sensing electrode that is based on the SO_2 concentration. The concentration of SO_2 can be calculated from 1 ppm to 1,000 ppm using the Nernst equation and the linear slope of the EMF (Rare-earth Information Center Insight, 2000b).

Sixteen years after the first quasicrystalline material was discovered, researchers created the first binary quasicrystal using metallic ytterbium and cadmium. Until the development of the cadmium-ytterbium compund ($Cd_{5.7}Yb$), it was believed that three or more elements were required to form a quasicrystal. Quasicrystals have long-range atomic ordering but do not have a periodic lattice like a normal crystal. The rare-earth quasicrystal exhibits primitive icosahedral (fivefold) symmetry, and unlike previously stable quasicrystals that are peritectic, it is a congruently melting compound (Tsai and others, 2000).

A rare-earth compound was developed that may be used as a scintillation detector. The lanthanum chloride compound was doped with 10% trivalent cerium and emits at 330 and 352 nanometers. The compound cerium-doped lanthanum chloride reportedly had better energy resolution and improved response times than the thallium-doped sodium iodine, the most commonly used scintillation detector material. Scintillation detectors are used to detect x rays and gamma rays by emitting an optical photon, which is a decay product that results from being struck by the incoming radiation. Future uses are likely to be in situations that require high-energy resolution (Loef and others, 2000, p. 1467-1468).

Components for the next generation of the U.S. Navy's hybrid sonar system are being developed using rare earths by Etrema Products, Inc. Using TERFENOL-D®, an iron-terbium-dysprosium alloy, the sonar system combines traditional piezeoceramic technology to produce an improved detector system for the Navy's new class of destroyers. The new hybrid materials reportedly created smaller sonar sound sources with higher power and broader bandwidth (Etrema Products, Inc., 2000b).

A new technique for separating rare earths was created using selective reduction and fractional distillation. The process creates separation factors two orders of magnitude greater than those for solvent extraction (SX) (liquid-liquid extraction). The separation is based on the fact that rare-earth trichlorides can be selectively reduced to dichlorides by specific dihalide-reducing agents. The unreduced trichlorides are distilled off creating a two-group separation (Uda and others, 2000). Although the authors claim a large advantage in separation, others believe the technique is a batch process, while SX is a continuous process. A potential drawback of the process was high energy consumption; the new technique's reduction process requires keeping the rare earth at 700° C to 800° C for several hours, followed by vacuum distillation at about 900° C, and deposited at 600° C to 700° C (Rare-earth Information Center Insight, 2001b).

Researchers developed a new process that will allow the rare earth cerium dioxide to be used as a sunscreen. The process coats the cerium dioxide particles with a 10 nanometer layer of boron nitride which eliminated agglomeration, passivated the cerium catalytic activity, and produced a slippery feel. When incorporated into an organic thin film, the coated cerium particles had higher transparency and greater UV blocking than either titanium dioxide or zinc oxide, the commonly used sunscreen ingredients. The improved sunscreen reportedly reduced sunburn, reduced skin aging, and reduced the potential causes of skin cancer (Rare-earth Information Center Insight, 2001a).

A red-emitting rare-earth phosphor (lithium-doped $Gd_2O_3:Eu^{3+}$) was developed by researchers in Korea for color flat panel field emission displays. The phosphor reportedly had higher cathodluminescence than eithereuropium-doped yttrium oxide and europium-doped yttrium oxysulfide, the widely used commercial phosphors. The addition of lithium provided two material advances: first, it improved the sol-gel produced morphology from irregularly shaped 0.5 micron shapes to consistently sized pseudospherical particles of 2 to 3 microns; and second, it is believed to become incorporated into the crystal structure as a coactivator, transferring electron beam energy to the trivalent europium (Eu^{3+}) and creating a higher efficiency than that of Eu^{3+} by itself (Park and others, 2000).

The U.S. Department of Energy (DOE) announced the construction of the world's first hybrid fuel cell manufactured by Siemens Westinghouse Power Corp. The 220-kilowatt fuel cell and microturbine powerplant incorporate rare earths. The powerplant uses a solid oxide fuel cell (SOFC) to convert natural gas directly to electricity with nearly zero emissions. Power is produced electrochemically by passing a hydrogen-rich

Digitized by Google

fuel over an anode and air over a cathode and separating the two by an electrolyte. In producing electricity, the only byproducts of the SOFC are heat, water, and carbon dioxide. Operating at 1,800° F, the SOFC's waste exhaust gas will power a microturbine and enhance performance by 10%. The culmination of the government-industry partnership program will be a 1-megawatt (1,000-kilowatt) fuel-cell-microturbine powerplant to be completed in late 2002 at Fort Meade, MD (U.S. Department of Energy, April 17, 2000, Department of Energy announces world's first "hybrid" fuel cell-turbine, accessed August 1, 2001, at URL http://fossil.energy.gov/techline/tl_fc_solidox_fat.html).

Research on the characterization and development of magnetic refrigeration alloys had been funded by the DOE. Scientists at the Ames Laboratory, where the materials were first developed, were rewarded with a 4-year project to study promising alloys. A team of 10 metallurgists, physicists, and chemists will explore the properties of the magnetic refrigeration group of gadolinium-silicon-germanium alloys. Ames Laboratory scientists Vitalij K. Pecharsky and Karl Gschneidner, Jr., first uncovered the energy-efficient characteristics of the alloys. A substantial advance in energy science, the use of these rare-earth alloys in automobile and home cooling and heating systems will provide substantial environmental benefits and energy savings (Ames Laboratory, 2000).

Outlook

The use of rare earths, especially in automotive pollution catalysts, permanent magnets, and rechargeable batteries, is expected to continue to increase as future demand for automobiles, electronics, computers, and portable equipment grows. Rare-earth markets are expected to require greater amounts of higher purity mixed and separated products to meet the demand. Strong demand for cerium and neodymium for use in automotive catalytic converters and permanent magnets is expected to continue throughout the decade. Future growth is forecast for rare earths in rechargeable Ni-MH batteries, fiber optics, and medical applications, including magnetic resonance imaging contrast agents, PET scintillation detectors, medical isotopes, and dental and surgical lasers. Long-term future growth is expected for rare earths in magnetic refrigeration alloys.

World reserves are sufficient to meet forecast world demand well into the 21st century. Several world-class rare-earth deposits in Australia and China have yet to be developed because world demand is currently [2000] being satisfied by existing production (Singer, 1995). World resources should be adequate to fulfill demand for the foreseeable future.

Domestic companies have shifted away from using naturally occurring radioactive rare-earth ores. This trend has had a negative impact on monazite-containing mineral sands operations worldwide. Future long-term demand for monazite, however, is expected to increase because of its abundant supply and its recovery as a low-cost byproduct. The cost and space to dispose of radioactive waste products in the United States are expected to continue to increase, severely limiting domestic use of low-cost monazite and other thorium-bearing rare-earth ores.

World markets are expected to continue to be very competitive based on lower wages and fewer environmental and permitting requirements. China is expected to remain the world's principal rare-earth supplier. Economic growth in several developing countries will provide new and potentially large markets in Southeast Asia and Eastern Europe.

The long-term outlook is for an increasingly competitive and diverse group of rare-earth suppliers. As research and technology continue to advance the knowledge of rare earths and their interactions with other elements, the economic base of the rare-earth industry is expected to continue to grow. New applications are expected to continue to be discovered and developed.

RECYCLING—METALS

By Staff

Introduction[1]

Metals are important, reusable resources. Although the ultimate supply of metal is fixed by nature, human ingenuity plays a role in determining quantity of supply available for use at any point in time by developing economic processes for the recovery of primary metal (i.e., from the Earth) and secondary metal (i.e., from the use process stream). The reusable nature of metals contributes to the sustainability of their use.

Recycling, a significant factor in the supply of many of the metals used in our society, provides environmental benefits in terms of energy savings, reduced volumes of waste, and reduced emissions associated with energy savings. Table 1 shows salient U.S. apparent supply and recycling statistics for selected metals. Apparent metal supply of 152 million metric tons (Mt) was valued at $44.0 billion in 2000. By weight, iron and steel accounted for 88.0% of apparent supply. By value, aluminum accounted for 36.0% of apparent supply and iron and steel accounted for 29.2%. Recycling contributed 80.7 Mt of metal, valued at about $18.2 billion, or over one-half of metal apparent supply by weight.

This report summarizes metal recycling. The U.S. Geological Survey publishes separate annual reviews for each of the metals summarized in this report; those reviews contain more detailed information about individual metals and recycling of those metals.

Primary indicates material from ore deposits; secondary, from recycled materials, including used products and residual materials from manufacturing. Recycling practices, and the description of those practices, vary substantially among the metal industries covered in this report. Generally, scrap is categorized as new or old, where new indicates preconsumer sources and old suggests postconsumer sources. The many stages of industrial processing that precede an end product are the sources of new scrap. For example, when metal is converted into shapes—plates, sheets, bars, rods, etc.—new scrap is generated in the form of cuttings, trimmings, and off-specification materials. When these shapes are converted to parts, new scrap is generated in the form of turnings, stampings, cuttings, and off-specification materials. Similarly, when parts are assembled into products, new scrap is generated. Once a product completes its useful product life, it becomes old scrap. Used beverage cans and junked automobiles are examples of old consumer scrap; used jet engine blades and vanes are an example of old industrial scrap. A wide variety of descriptive terms including home scrap, mill scrap, purchased scrap, prompt scrap, etc. have evolved to describe scrap generated by a wide variety of industry practices.

Aluminum[2]

Various forms of aluminum scrap are recovered by almost every segment of the domestic aluminum industry. Integrated primary aluminum companies, independent secondary smelters, fabricators, foundries, and chemical producers are known to recover aluminum from scrap. Integrated primary aluminum companies and independent secondary smelters, however, are the major consumers of scrap.

The independent secondary aluminum smelters consume scrap and produce alloys for the diecasting industry. A cursory look at the distribution of these smelters in the United States reveals a heavy concentration of smelters in the automotive and appliance manufacturing areas of the country.

The other major consumers of aluminum scrap are the integrated aluminum companies. The integrated companies frequently purchase scrap from their industrial customers directly or on a contract-conversion basis. Major integrated aluminum companies also operate can recycling programs and have established thousands of collection centers around the country for used aluminum beverage cans.

Used beverage can (UBC) scrap is the major component of processed old aluminum scrap, accounting for approximately one-half of the old scrap consumed in the United States. Most UBC scrap is recovered as aluminum sheet and manufactured into aluminum beverage cans. Most of the other types of old scrap are recovered in the form of alloys used by the diecasting industry; the bulk of these die casts is used by the automotive industry.

Aluminum recovered from purchased scrap decreased by 7% in 2000 compared with that of 1999. Of the 3.45 Mt of recovered metal, 60% came from new (manufacturing) scrap, and 40%, from old (discarded aluminum products) scrap.

According to figures released by the Aluminum Association Inc., the Can Manufacturers Institute, and the Institute of Scrap Recycling Industries, Inc., 62.6 billion aluminum UBCs were recycled in the United States in 2000, for a beverage can recycling rate of 62.1% or nearly 2 of every 3 aluminum cans shipped. Although the recycling rate was slightly lower than the 1999 rate of 62.5%, this was the 12th consecutive year that the U.S. recycling rate exceeded 60%. According to the organizations, the average aluminum beverage can produced domestically is comprised of more than 51% recycled content (Aluminum Association Inc., 2001).

Purchase prices for aluminum scrap, as quoted by American Metal Market, fluctuated during the year but closed at lower levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 47.5 to 48.5 cents per pound; old sheet and cast aluminum, 38.5 to 39.5 cents per pound; and clean, dry aluminum turnings, 40 to 41 cents per pound.

Aluminum producers' buying price range for processed and delivered UBCs, as quoted by American Metal Market, also closed lower at yearend. The price range began the year at 57 to 59 cents per pound and closed the year at 53 to 54 cents per pound. Resource Recycling published a monthly transaction

price for aluminum UBCs in its Container Recycling Report. During the year, the monthly average decreased significantly from 62.9 cents per pound in January to 53.9 cents per pound in December. However, the annual average price for aluminum UBCs in 2000 of 57.7 cents per pound was higher than the 1999 annual average of 50.6 cents per pound.

The yearend indicator prices for selected secondary aluminum ingots, as published in American Metal Market, also decreased significantly compared with those of 1999. The closing prices for 2000 were as follows: alloy 380 (1% zinc content), 68.7 cents per pound; alloy 360 (0.6% copper content), 74.1 cents per pound; alloy 413 (0.6% copper content), 73.8 cents per pound; and alloy 319, 72.7 cents per pound. Platt's Metals Week published an annual average U.S. price of 65.6 cents per pound for A-380 alloy (3% zinc content). The average annual London Metal Exchange (LME) cash price for a similar 380 alloy was 55.2 cents per pound.

Beryllium[3]

Beryllium is used in many applications where such properties as light weight and stiffness are important. In 2000, the United States, one of only three countries that processed beryllium ores and concentrates into beryllium products, supplied most of the rest of the world with these products.

Beryllium-copper alloys, most of which contain approximately 2% beryllium, are used in a wide variety of applications and account for the largest share of annual U.S. apparent consumption on a beryllium-metal-equivalent basis. Beryllium metal is used principally in aerospace and defense applications, and beryllium oxide serves mainly as a substrate for high-density electronic circuits. Because of its high cost, beryllium use is restricted to those applications in which its properties are crucial. Such substitutes as graphite composites, phosphor bronze, steel, and titanium are available for certain beryllium applications but with a substantial loss in performance.

In 2000, U.S. apparent consumption of beryllium totaled about 300 metric tons. Unknown quantities of new scrap generated in the processing of beryllium metal and beryllium-copper alloys were recycled. The new scrap generated during the machining and fabrication of beryllium metal and alloys was returned to the metal-alloy producers for recycling. The beryllium in beryllium-copper fabricated parts was so widely dispersed in products, and so highly diluted when those products were recycled, that it was essentially dissipated. Additionally, small quantities of obsolete military equipment containing beryllium were recycled (Cunningham, 2001a; Petkof, 1985).

Cadmium[4]

The amounts of secondary or recycled cadmium are difficult to estimate for several reasons. In the recycling of baghouse dusts from lead and copper smelters, for example, the recovered cadmium subsequently enters primary cadmium production circuits at zinc refining operations and is included in the production statistics for primary cadmium metal. There are no firm figures on the amounts of cadmium recovered from sources such as electroplating waste, filter cakes, sludges, and other cadmium-containing wastes. The total amount of secondary cadmium, estimated by the International Cadmium Association, was about 10% of 2000 world primary production.

Recycling of cadmium is a young but growing industry spurred by environmental concerns and regulatory moves to limit dissipation of cadmium from discarded cadmium products. Because about three-fourths of cadmium is used in nickel-cadmium (NiCd) batteries, and because batteries are easy to recycle, most of the secondary cadmium comes from spent NiCd batteries. Another form of old scrap that is easy to recycle is the flue dust generated during recycling of galvanized steel scrap in electric arc furnaces. Most of the new scrap for recycling is generated during manufacturing processes, such as die casting. All other applications use materials that are low in cadmium concentration and, therefore, are difficult to recycle for cadmium. Consequently, much of this cadmium is dissipated.

In 2000, the annual rate of secondary production in the United States amounted to about 200 metric tons (t). The International Metals Reclamation Co. Inc. (Inmetco) in Ellwood City, PA, is the only cadmium recycling company in the United States. Although the plant was established in 1978, cadmium recovery did not begin until 1996. Large batteries, usually weighing more than 2 kilograms (kg) and containing an average of 15% cadmium, are emptied of their electrolyte and dismantled. Detached cadmium plates then go directly into the furnace, using the high temperature metal recovery process (HTMR). Cadmium in smaller sealed batteries is recovered by burning off the castings and separators at a lower temperature than used in the HTMR process. The resulting 99.95% pure cadmium is shipped to battery manufacturers for reuse.

The future of cadmium recycling, and of cadmium industry in general, could be profoundly affected by a proposed ban of cadmium use in Europe by the European Commission. According to the European Union's Directive 2000/60/EC on water, the ban on Ni-Cd batteries is to start in 2008, if approved by the European Parliament.

Chromium[5]

The major end use of chromium is in stainless steel, and this is the major form in which chromium is recycled. Chromite ore is smelted to make ferrochromium, a chromium-iron alloy that results from the removal of oxygen from chromite. Ferrochromium is then added to iron at steel-producing plants to make the iron-chromium alloy that is commonly called stainless steel. Stainless steel scrap can substitute for ferrochromium as a source of chromium. Stainless steel is composed of two broad categories—austenitic and ferritic. The names are related to the molecular structure of the steel but also identify which grades require nickel (austenitic) and which do not (ferritic). Nickel content increases the price of the alloy and its resulting scrap.

Scrap is generated during the manufacturing process (new scrap) and as a result of recycling obsolete equipment (old scrap). Scrap from these sources is collected and sorted by grade (i.e., chemical composition) in scrap yards. Scrap brokers

play a role in moving material from where it is recovered to where it is consumed. The steel industry consumes stainless steel scrap as a source of chromium and nickel. Thus chromium units are recycled when stainless steel is reused. A study of domestic stainless steel found that its average chromium content is about 17% (Papp, 1991, p. 1).

Cobalt[6]

Cobalt-bearing scrap is generated during manufacture and/or following use in these applications—catalysts used by the petroleum and chemical industries; cemented carbides used in cutting and wear-resistant applications; rechargeable batteries; and superalloys, magnetic and wear-resistant alloys, and tool steels. Depending on the type and quality of the scrap, it might be recycled within the industry sector that generated it, processed to reclaim the cobalt as a cobalt chemical or metal powder, downgraded by using it as a substitute for nickel or iron in an alloy with a lower cobalt content, or processed to an intermediate form that would then either be further refined or downgraded. The products of recycled cobalt scrap include alloys; mixed metal residues; pure cobalt metal, metal powder, or chemicals; and tungsten carbide-cobalt powders.

In 2000, scrap consumption reported by U.S. cobalt processors and consumers was 2,550 t of contained cobalt, a decrease of 6% from the 2,720 t consumed in 1999. U.S. imports of cobalt waste and scrap increased by 41% to 550 t, gross weight, valued at $4.1 million. Seven countries supplied more than 90% of these materials—the United Kingdom (43%), France (13%), Germany (11%), Canada (10%), Japan (6%), and Argentina and Belgium (5% each). U.S. exports of cobalt waste and scrap are reported in combination with exports of unwrought cobalt metal and metal powders.

Copper[7]

According to data compiled by the International Copper Study Group (International Copper Study Group, 2001, p. 16), estimated world production of secondary refined copper increased by about 3% in 2000 to 2.1 Mt and accounted for 14.2% of global world refined copper production. According to data compiled by the World Bureau of Metal Statistics (World Bureau of Metal Statistics, 2001, p. 42) and adjusted by the U.S. Geological Survey, an additional 3.13 Mt of copper was recovered from the direct remelting of copper scrap, a decline of about 60,000 t from that of 1999 revised data. Secondary refined production in the United States continued its downward trend, declining by more than 20,000 t (9%) in 2000, based on revised data. Secondary refined production has fallen by about 190,000 t (47%) since 1997 owing to contraction of the secondary smelting/refining industry. Copper recovered in alloys and chemicals (direct melt scrap) was essentially unchanged at 1.10 Mt.

Copper scrap prices generally followed the trend in refined copper prices, though the discount for various grades of scrap tended to narrow with lower prices. Despite growing global inventories, copper prices in January continued the upward trend begun in mid-1999, and rose to their highest level in almost 2 years. The COMEX spot price averaged $0.85 per pound in January. However, prices weakened beginning in March, the COMEX price averaging only $0.80 in the March to June period. In response to declining global inventories, the average monthly COMEX price climbed to $0.91 in September. Prices weakened and fluctuated during the fourth quarter of the year, the COMEX price averaging $0.86 and finishing the year at $0.85. The average annual COMEX price of $0.84 was at its highest level since 1997. While the discount to COMEX prices for No. 1 (brass mill) scrap and No. 2 (refiners) scrap averaged 3.3 cents per pound and 19.0 cents per pound, respectively, for the year, margins narrowed to below 3 cents and 17.5 cents per pound during the period of low copper prices at midyear and rose to 4.6 cents and 19 cents, respectively, during December.

According to data compiled by the International Copper Study Group (2001, p. 40-43), global trade in copper scrap increased significantly in 2000, principally owing to increased shipments from the United States, which rose from 315,000 t (estimated copper content 258,000 t) to 485,000 t (estimated copper content 395,000 t). The United States was the largest international source for copper scrap, accounting for about 17% of all reported scrap exports. China (including Hong Kong), which reported copper scrap receipts of 2.6 Mt, up from 1.8 Mt in 1999, was the largest recipient of scrap, accounting for about 54% of reported global scrap imports. It was also the largest recipient of U.S. scrap, accounting for 46% of all scrap exports. Data on world scrap trade are incomplete, however, with reported imports generally exceeding reported exports. In the case of China, it is believed that import data may include some very low-grade or misclassified material. In 2000, U.S. imports of copper scrap of 112,000 t were essentially unchanged. Canada and Mexico were the leading sources for U.S. imports of copper and copper alloy scrap, accounting for 79% of imports in 2000.

During 2000, two secondary smelters and three fire refineries processed scrap to recover unalloyed copper products in the United States. Scrap was also consumed in relatively small quantities at several of the primary smelters. One fire refinery in Missouri, Warrenton Refining Co., which had closed in 1999, reopened under new ownership.

In May, Southwire Co. closed its secondary smelter and associated electrolytic refinery, in Carrollton, GA. Southwire continued to operate its rod mill housed within its Copper Division Southwire (CDS). Sixteen months prior, as part of a restructuring plan aimed at lowering its costs, Southwire had unsuccessfully placed its Carrollton copper smelter/refinery operations on the market. Southwire cited economic factors, including the continued cost of compliance with environmental regulations in the metro-Atlanta area, for the closure of copper smelting operations. CDS was constructed in 1972, at a time when primary producers exerted greater control over copper prices. As part of the closure justification, Southwire cited the advent of worldwide commodity prices and their own "strong buying position" as leverage in meeting future raw material needs (Southwire Co., 2000). Southwire processed a mixture of imported blister and copper scrap at its smelter to produce anode for electrolytic refining. Southwire, which had a capacity to produce 140,000 tons per year (t/yr), of refined copper, was one of two remaining secondary smelters in the United States, two other smelters having closed in the preceding 3 years.

Southwire closed its other secondary copper smelter in Gaston, SC, at the end of 1994, also citing the high cost of environmental compliance as the reason for closure.

Direct melt scrap, principally alloy scrap, was consumed at about 35 brass mills, 20 alloy ingot makers, and 500 foundries, chemical plants, and miscellaneous consumers. Of the total copper recovered from copper-, aluminum-, nickel-, and zinc-base scrap, copper smelters and refiners recovered 16%; brass mills, 64%; brass and bronze ingot makers, 9%; and miscellaneous manufacturers (including aluminum and steel alloy producers), foundries, and chemical plants, 11%. Alloyed copper products accounted for about 83% of the total copper recovered from scrap.

In 2000, copper recovered from all refined or remelted scrap (about 28% from old scrap and 72% from new scrap) composed 32% of the total U.S. copper supply and had an equivalent refined value of $2.6 billion. Despite a slight decline in copper recovery from scrap, the equivalent refined value of copper recovered from scrap rose by about 15% in 2000 owing to higher average copper prices. Copper recovered from old scrap continued its 3-year decline, falling 5% to 363,000 t and was down by 27% from that recovered in 1997. Copper recovered from new scrap increased nominally to 952,000 t, reflecting an overall increase in brass mill shipments to the domestic market.

Gallium[8]

Because of the low yield in processing gallium to optoelectronic devices or integrated circuits, substantial quantities of new scrap are generated during the various processing stages. These wastes have varying gallium and impurity contents, depending upon the processing step from which they result. Gallium arsenide (GaAs)-based scrap, rather than metallic gallium, represents the bulk of the scrap that is recycled. During the processing of gallium metal to a GaAs device, waste is generated in several stages. If the ingot formed does not exhibit single crystal structure or if it contains excessive quantities of impurities, the ingot is considered to be scrap. Also, there is some GaAs that remains in the reactor after the ingot is produced, which may be recycled. During the wafer preparation and polishing stages, significant quantities of wastes are generated. Before wafers are sliced from the ingot, both ends of the ingot are cut off and discarded, because impurities are concentrated at the tail end of the ingot, and crystal imperfections occur at the seed end. These ends represent up to 25% of the weight of the ingot. As the crystal is sliced into wafers, two types of wastes are generated—saw kerf, which is essentially GaAs sawdust, and broken wafers. When the wafers are polished with an abrasive lapping compound, a low-grade waste is generated. During the epitaxial growth process, various wastes are produced, depending on the growth method used. Because GaAs is a brittle material, wafers may break during the fabrication of electrical circuitry on their surfaces. These broken wafers also may be recycled. Gallium content of these waste materials varies from less than 1% to as much as 99.99%. In addition to metallic impurities, the scrap may be contaminated with other materials introduced during processing such as water, silicone oils, waxes, plastics, and glass (Kramer, 1998, p. 15).

In processing GaAs scrap, the material is crushed, if necessary, then dissolved in a hot acidic solution. This acid solution is neutralized with a caustic solution to precipitate the gallium as gallium hydroxide, which is filtered from the solution and washed. The gallium hydroxide filter cake is redissolved in a caustic solution and electrolyzed to recover 99.9% to 99.99% gallium metal (Kramer, 1998, p. 15).

Some GaAs manufacturers may recycle their own scrap, or scrap may be sold to metal traders, to a company that specializes in recycling GaAs, or to the GaAs manufacturer's gallium supplier, who can recover the gallium and return it to the customer. Generally the prices commanded by GaAs scrap parallel the price fluctuations of 99.99%-pure gallium metal. Also, prices are dependent on the type and gallium content of the scrap. GaAs scrap that is recycled is new scrap, which means that it has not reached the consumer as an end product, and it is present only in the closed-loop operations between the companies that recover gallium from GaAs scrap and the wafer and device manufacturers (Kramer, 1998, p. 15).

Gold[9]

Old scrap consists of gold-containing products that have been discarded after use, and generally contributes 13% to 25% of the total U.S. supply of gold. New scrap is generated during manufacturing processes and, for the most part, remains the property of the manufacturers; it is not counted as part of the market supply. The scrap component of the gold supply is perhaps the most difficult of all metal supply components to quantify. In many areas of the world, especially in those areas where the holding of gold is encouraged by tradition, secondary gold, especially that derived from gold jewelry, changes hands both locally and internationally, often using goldsmiths as collection sites. This flow is often in response to variations in the gold price and usually cannot be followed statistically.

A considerable quantity of scrap is generated during manufacturing, but because of tight controls over waste materials in precious metals plants, nearly all of this "home-generated" scrap can be recovered. Probably the greatest loss in gold fabrication takes place in gold-plating plants where fouled or depleted solutions are sometimes discarded. Some old scrap, however, is lost because, in practice, gold cannot be economically recovered from all manufactured products.

Gold-bearing scrap is purchased on the basis of gold content, as determined by analytical testing and the market price for gold on the day that the refined product is available for sale. Processing charges and adjustments for processing losses are deducted from the total value in settling payments. Aside from dealer-processors and refiners, scrap gold has no market. The Federal Trade Commission requirement for karat identification of jewelry alloys requires gold refiners to identify the chemical analysis of the alloys they purchase and to separate the constituents of scrap to assure meeting karat standards [Public Law 226, An act forbidding the importation, exportation, or carriage in interstate commerce of falsely or spuriously stamped articles of merchandise made of gold or silver or their alloys, and for other purposes, 1906, 59th Congress, 1st Session,

Revised Statute U.S. v. 34, part 1, June 13, p. 260].

Refiners throughout the world recover secondary gold from scrap. In the United States, about two-thirds of the scrap comes from manufacturing operations, and the remainder comes from old scrap in the form of such items as discarded jewelry and dental materials, used plating solutions, and junked electronic equipment. A few dozen companies, out of several thousand companies and artisans, dominate the fabrication of gold into commercial products. Most of the domestic scrap is processed by refiners centered in New York, NY, and Providence, RI; refiners are also concentrated in areas of California, Florida, and Texas, although the current trend seems to be toward a less centralized industry. Scrap dealers may process the scrap and then ship the upgraded product to refiners and fabricators for further treatment and refining. The U.S. Department of Defense (DOD) recovers significant quantities of gold from military scrap (Laura Green, Precious Metals Specialist, Defense Logistics Agency, oral commun., 1998). Other Federal Government agencies either participate in the DOD recovery program or have one of their own. DOD awarded contracts to manage more than 11 million kilograms of electronic scrap anticipated to be collected through the middle of 2000 (American Metal Market, 2000a).

Domestic consumption of new and old gold scrap was 42,000 kg and 70,000 kg respectively. These data were collected in 2000 by the U.S. Geological Survey, and include 30,000 kg of old imported scrap. In 2000, U.S. exports of gold scrap increased, after 2 years of decrease, while imports stayed at their highest level since 1995. As it has been for many years, the United States was a net exporter of gold scrap in 2000.

Prices for gold waste and scrap imported and exported in 2000 averaged $74 and $226 per troy ounce, respectively; at the same time, the average price for gold was $280 per ounce (Platts Metals Week, 2001).

Indium[10]

Domestic recovery of secondary indium remained low for the 4th year since the unusually high level of 1996, when high prices encouraged the recycling of more old scrap. In 2000, as is typical in the United States, most of the secondary indium was recovered from new scrap. The actual quantity of secondary indium recovered is not known, but it was small; only in 1996 was the quantity significant following a $12 per troy ounce price increase in 1995 that resulted from concern over supply. In 1996, recycling provided much of domestic supply (Fineberg, 1996), and imports decreased more than 50%.

In Japan, however, recycling has maintained its importance in recent years (McColloch, 2000). In 2000, indium demand reached a record 335 t in 2000 in Japan, with slightly more than one-half of the material coming from recycled scrap (Roskill's Letter from Japan, 2001).

Iron and Steel[11]

Iron, including its refined product steel, is the most widely used of all the metals, and the recycling of iron and steel scrap (ferrous scrap) is an important activity worldwide. Iron and steel products are used in many construction and industrial applications, such as in appliances, bridges, buildings, containers, highways, machinery, tools, and vehicles. Because it is economically advantageous to recycle iron and steel by melting and recasting into semifinished forms for use in the manufacture of new steel products, a significant industry has developed to collect used and obsolete iron and steel products, and the ferrous scrap generated in steel mills and steel-product manufacturing plants. The North American steel industry's overall recycling rate is nearly 64% (Steel Recycling Institute, [undated], A few facts about steel—North America's #1 recycled material, accessed August 23, 2001, at URL http://www.recycle-steel.org/fact).

The vast quantity of ferrous scrap available for recycling comprises home, prompt, and obsolete scrap. Prompt, or industrial, scrap is generated from manufacturing plants that make steel products. Its chemical and physical characteristics are known, and it is usually transported quickly back to steel plants for remelting to avoid storage space and inventory control costs. Home or mill scrap is generated within the steel mill during production of iron and steel. Trimmings of mill products and defective products are collected and quickly recycled back into the steel furnace because their chemical compositions are known. The availability of home scrap has been declining as new and more efficient methods of casting have been adopted by the industry. Obsolete, old, or post-consumer scrap is also available for recycling. The largest source is junked automobiles, followed by demolished steel structures, wornout railroad cars and tracks, appliances, and machinery. Because of the wide variety of chemical and physical characteristics, obsolete scrap requires more preparation, such as sorting, detinning, and dezincing.

In the United States, the primary source of obsolete steel is the automobile (Steel Recycling Institute, [undated], Recycling scrapped automobiles, accessed August 23, 2001, at URL http://www.recycle-steel.org/cars/autorec.html). Of the ferrous metal used to make a typical 2000 U.S. family vehicle, about 44% was recycled metal. About 12,000 car dismantlers and 3,000 scrap processors produced more than 14 Mt of iron and steel scrap from about 14 million automobiles for recycling in 2000—enough steel to produce 48 million steel utility poles, which are one-third of the utility polls in the United States (Steel Recycling Institute, [undated], Recycling scrapped automobiles, accessed August 23, 2001, at URL http://www.recycle-steel.org/cars/autorec.html).

Manufactured steel products have a wide range of physical and chemical characteristics according to relative contents of the trace elements carbon, chromium, cobalt, manganese, molybdenum, nickel, silicon, tungsten, and vanadium. Also, some steel products are coated with aluminum, chromium, lead-tin alloy, tin, or zinc. For these reasons, scrap dealers must carefully sort the scrap they sell and steelmakers must be careful to purchase scrap that does not contain undesirable elements, or residuals, that exceed acceptable levels, which vary according to the product being produced.

Steel mills melt scrap in basic-oxygen furnaces (BOF), electric arc furnaces (EAF), and to a minor extent, in blast furnaces. The proportion of scrap in the charge in a BOF is limited to less than 30%, whereas that in an EAF can be as much as 100%. Steel and iron foundries use scrap in EAFs and cupola

[10]Prepared by Robert D. Brown, Jr. (703) 648-4984; Fax (703) 648-7757.

Digitized by Google

furnaces. In 1999, BOFs were used to produce 53% of total steel in the United States while using only 28% of total scrap consumed (American Iron and Steel Institute, 2000, p. 86). During the same period, EAFs produced 47% of total steel while using 71% of total scrap consumed. Scrap was also melted in blast furnaces and other types of furnaces.

Iron and steel scrap is an additional resource for steelmakers that is more than just economically beneficial. Recycling conserves natural resources, energy, and landfill space. Recovery of 1 t of steel from scrap conserves an estimated 1,030 kg of iron ore, 580 kg of coal, and 50 kg of limestone. Each year, steel recycling saves the energy equivalent to electrically power about one-fifth of the households in the United States (about 18 million homes) for 1 year (Steel Recycling Institute, [undated], Recycling scrapped automobiles, accessed July 17, 2000, at URL http://www.recycle-steel.org/cars/autorec.html).

During 1999, steel recycling rates were 95% for automobiles, 95% for construction structural beams and plates, 84% for appliances, 58% for steel cans, and nearly 64% overall (Steel Recycling Institute, [undated], A few facts about steel—North America's #1 recycled material, accessed August 23, 2001, at URL http://www.recycle-steel.org/fact).

Ferrous scrap is an important raw material for the steel and foundry industries. Because scrap comes from such sources as old buildings, industrial machinery, discarded cars and consumer durables, and manufacturing operations, the mature industrialized economies are the main exporters of scrap. The main trade flows of scrap are from the heavily industrialized and developed countries of North America and Europe to lesser developed steelmaking countries. The United States was not the leading exporting country of iron and steel scrap in 1999, as reported by the International Iron and Steel Institute (2000, p. 102). Germany took the lead, followed by Russia, the United States, Ukraine, Japan, France, the United Kingdom, and the Netherlands. The four most significant importing nations were, in decreasing order of importance, Turkey, the Republic of Korea, and the United States (International Iron and Steel Institute, 2000, p. 104).

The U.S. trade surplus for all classes of ferrous scrap was 2.2 Mt in 2000 (U.S. Census Bureau, unpub. data, 2000). Total U.S. exports of carbon steel and cast-iron scrap went to 55 countries and totaled 4.5 Mt. The largest tonnages went to the Republic of Korea, Canada, Mexico, China, and Taiwan. Total U.S. exports of stainless steel scrap went to 43 countries and consisted of 470,000 t. The largest tonnages went to the Republic of Korea, Taiwan, Canada, and Japan. U.S. exports of alloy steel scrap (excluding stainless steel) were shipped to 46 countries and consisted of 815,000 t. The largest tonnages went to Canada and Mexico.

Lead[12]

About 77% of the 1.46 Mt of refined lead produced in the United States in 2000 was recovered from recycled scrap, of which a major source was spent lead-acid storage batteries. The recycled batteries consisted of the starting-lighting-ignition type used in automotive applications, as well as the industrial-type used in numerous applications such as uninterruptible power-supply equipment, load-leveling equipment for commercial electrical power systems, industrial forklifts, mining vehicles, golf cars and other human and materials transport vehicles, lawn equipment, airport ground-support equipment, floor sweepers and scrubbers, and bicycles. About 5% of the recycled lead was recovered from other lead-based sources including solder, cable covering, building construction materials, and drosses and residues (new scrap) from primary smelter-refinery operations.

Recycled lead was produced domestically by 18 companies operating 26 lead recovery plants. Of the 1.12 Mt of lead recycled in 2000, about 98% was produced by 7 companies operating 15 secondary smelter-refineries in Alabama, California, Florida, Indiana, Louisiana, Minnesota, Missouri, New York, Pennsylvania, Tennessee, and Texas. Most of the recycled lead was recovered either as soft lead or lead alloys to be reused in the manufacture of lead-acid storage batteries. Consumption of lead in storage batteries accounted for 87% of the reported consumption of lead in the United States in 2000.

During the period 1996 to 2000, the United States exported an average of about 92,000 t/yr of lead-bearing scrap, including battery as well as nonbattery forms. Only minimal quantities of lead-bearing scrap were imported during this period. The spot price for smelters' heavy soft lead scrap averaged about 21 cents per pound during this period. The average North American Producer price for refined lead was about 45 cents per pound.

During 2000, the recovery of lead from spent lead-acid batteries and other lead scrap at secondary smelters was sufficient to meet about 76% of the demand for lead in the manufacture of new batteries. The market price for whole scrap batteries averaged about 5.5 cents per pound near the end of 2000, translating to a lead price of 11 cents per pound, assuming that lead accounted for about 50% of battery weight. The failure rate of automotive batteries remained fairly level during most of the year, as sustained temperature extremes were absent in the more heavily populated regions of the United States. In December, however, extreme winter conditions in many parts of the United States increased the level of automotive battery failures, but the usual associated increase in demand for lead by the battery manufacturers was tempered by the high level of inventories of new replacement batteries held by the manufacturers. Production of lead at secondary smelters increased by about 2% compared with production in 1999. Stocks of refined secondary lead held by producers and battery manufacturers increased appreciably at yearend.

In January, Johnson Controls, Inc., Milwaukee, WI, signed new tolling agreements to recover lead from spent lead-acid batteries for its battery business on the west coast of the United States. Reportedly, the processing of the spent battery units was to be divided between the secondary smelter plants of RSR Corp. at City of Industry, CA, and GNB Technologies, Inc. at Vernon, CA. The tolling agreements were expected to be in effect for 1 year (Ryan's Notes, 2000a).

Exide Corp., Reading, PA, closed its Laureldale, PA, battery manufacturing plant at the end of June. According to company officials, the action was taken as a consolidation measure, thus achieving higher capacity utilization at its remaining battery manufacturing plants (Ryan's Notes, 2000b).

In late September, Exide Corp. completed its acquisition of GNB Technologies, Inc., Atlanta, GA. As a result of the purchase, and following shareholder approval, Exide Corp. was

[12]Prepared by Gerald R. Smith (703) 648-4983; Fax (703) 648-7757.

Digitized by Google

renamed Exide Technologies. GNB had supplied a significant portion of the industrial batteries used in the North American market. Thus, the purchase allowed Exide to reenter the North American industrial battery business. GNB also was a leading supplier of automotive batteries for both the original equipment and replacement battery markets. Following the acquisition, Exide also announced several initiatives designed to restructure the newly formed company: consolidation of automotive battery manufacturing facilities in the United States; consolidation of industrial battery operations in Europe; closure of several distribution centers and branch locations by the end of 2000; and downsizing and relocation of new headquarters to Princeton, NJ, from Reading, PA (Exide Technologies, 2000).

In December, Exide Technologies, Princeton, NJ, reported plans to reopen and upgrade its battery manufacturing plant in Maple, Ontario. Exide expected to produce industrial-type lead-acid batteries at the plant for the growing motive power and telecommunications markets. One type of battery to be produced at the Maple plant is used as a back-up power source for Internet and wireless driven voice, data, and multimedia networks. The company had closed the Maple plant, originally used to manufacture automotive-type lead-acid batteries, after Exide's acquisition of GNB Technologies, Inc. Exide's investment in the plant will extend over a 12-month period with initial production expected early in 2001 and full production by yearend (Platt's Metals Week, 2000).

Magnesium[13]

New magnesium-base scrap typically is categorized into one of four types. Type I is high-grade scrap, generally material such as gates, runners, and drippings from diecasting operations that is uncontaminated with oils. Types II, III, and IV are lower graded materials. Type II is oil-contaminated scrap, type III is dross from magnesium-processing operations, and type IV is chips and fines. The most desirable type of scrap is type I. Most of the type I scrap is generated during diecasting magnesium alloys. This scrap is either reprocessed at the diecasting facility or sold to a scrap processor. The other types of scrap are either sold to a scrap processor or are used directly in steel desulfurization. Old magnesium-base scrap, or postconsumer scrap, consists of such material as automotive parts, helicopter parts, lawnmower decks, used tools, and the like. This scrap is sold to scrap processors.

In addition to magnesium-base scrap, significant quantities of magnesium are contained in aluminum alloys that also can be recycled. Although some magnesium is lost in scrap processing, a significant quantity of the magnesium is recycled with the aluminum alloy. New aluminum-base scrap that is recycled consists, in descending order of importance, primarily of solids, borings and turnings, dross and skimmings, and other material, which includes foil and can-stock clippings. Because the main aluminum product that contains magnesium is beverage cans, the principal magnesium-containing, aluminum-base scrap is can-scrap skeleton from lids and can sheet clippings. This represents about one-half of the overall magnesium-containing, aluminum-base scrap.

Old aluminum-base scrap consists of a variety of materials, but the most important magnesium-containing component is UBCs. Because of the high recycling rate, UBCs represent about three-quarters of the magnesium-containing, old aluminum-base scrap that is reprocessed. The magnesium in old and new aluminum-base scrap is not separated from the aluminum alloy when it is recycled; rather, it is retained as an alloying component.

Magnesium scrap arrives at the recycler either loose on a dump trailer or in boxes on a van-type trailer. Sorting the magnesium-base scrap correctly is crucial to producing a product that meets specifications. Because magnesium and aluminum closely resemble each other, a load of magnesium scrap may contain some aluminum scrap as well. The scrap is visually inspected, and one of the ways to separate the magnesium from the aluminum scrap is by scratching the metal with a knife. Magnesium tends to flake, whereas the softer aluminum tends to curl. After separating the aluminum-base scrap and any other foreign material, the magnesium scrap is sorted according to alloy.

In melting, sorted scrap is charged to a steel crucible, which is heated to 675° C. As the scrap at the bottom begins to melt, more scrap is added. The liquid magnesium at the bottom is covered with a flux or inhibitive gas to control surface burning. After any alloying elements are added, such as aluminum, manganese, or zinc, and melting is complete, molten magnesium is transferred to ingot molds by hand ladling, pumping, or tilt pouring (Wentz and Ganim, 1992).

In addition to melting, magnesium scrap may be recycled by direct grinding of the scrap into powder for iron and steel desulfurization applications. This method is limited to using only specific types of clean scrap. Drosses and other contaminated scrap are not used because they can introduce impurities into the finished product, and these types of scrap can increase the danger of fire in the direct grinding (Dahm, 2000).

Manganese[14]

Scrap recovery specifically for manganese is insignificant. To a large extent, it is recycled incidentally as a minor component within scrap of another metal, particularly steel and, to a much lesser degree, aluminum. High-manganese (Hadfield) steel, which has a manganese content of about 12%, is recovered for its manganese content, but the quantity of such scrap is believed to be well below 1% of the total quantity of purchased steel scrap. Recycling of aluminum and steel are discussed in the respective sections of this chapter. Manganese is ubiquitous throughout the various grades of steel, which, on average, contains about 0.7% manganese (Jones, 1994, p. 10). Manganese that is recycled to steelmaking within steel scrap largely is lost because of its removal in the decarburization step of steelmaking, but needs to be added back. Manganese is recycled in the aluminum industry as a component of scrap of certain manganese-bearing aluminum alloys, principally as UBC in which the manganese content is about 1%. Melting and processing of aluminum is nonoxidizing toward manganese, so that most of the manganese is retained. The amount of manganese being recycled in the aluminum industry is estimated to be in the vicinity of 1% of manganese apparent consumption.

In the future, small additional amounts of manganese could be recovered through widespread recycling of dry cell batteries (Watson, Andersen, and Holt, 1998).

Mercury[15]

In response to health and environmental concerns, secondary mercury is recovered from a variety of source materials as mandated by Federal and State regulations to reduce the discharge and disposal of mercury-containing products. Electronic devices including rectifiers, switches, thermostats, and relays; dental amalgams; batteries; and other instruments such as thermometers, are processed to recover any contained mercury. However, the largest source of secondary mercury remains the spent catalysts used in the production of chlorine and caustic soda. Three companies, one each in Illinois, Minnesota, and Pennsylvania, produce the bulk of secondary mercury in the United States. Mercury waste generated in the manufacturing of products (new scrap) is either reused internally or collected for reprocessing.

Molybdenum[16]

Catalysts containing about 3,400 t of molybdenum were recycled. The U.S. superalloys producers consumed about 460 t of pure molybdenum metal scrap. Also molybdenum contained in alloy iron and steel scrap was recycled to produce new alloyed steel products. The amount of molybdenum consumed to produce these products was not recorded.

Nickel[17]

Austenitic stainless steel scrap is the largest source of secondary nickel for the United States, accounting for about 83% of the 84,000 t of nickel reclaimed in 2000. An additional 2% came from the recycling of alloy steel scrap. The combined 85% represents not only scrap used in raw steel production, but also lesser amounts of scrap consumed by steel and iron foundries, as well as nickel reclaimed from stainless steelmaking residues (e.g., furnace dust, grindings, and mill scale).

Western World demand for austenitic scrap increased substantially in the first half of 2000 because of higher prices for primary nickel. The price rise and global scrap drawdown were the result of a shortage of cathode and briquets. In the second half of 2000, recessionary forces in the United States triggered a dropoff in domestic stainless steel production and a slackening of deliveries of austenitic scrap to U.S. steelworks. The U.S. steel industry produced a near-record 1.24 Mt, gross weight, of austenitic stainless steel in 2000 despite the second half dropoff. Production of austenitic stainless steel in the European Union (EU) and Japan rose to 3-year highs, spurring international trade in austenitic scrap (Hunter, 2001).

Demand in the Western World for primary nickel was estimated to be a record 1.029 Mt in 2000, up slightly from 1.004 Mt in 1999 (International Nickel Study Group, 2001a, p. 3-12). The Western World supply of primary nickel also increased, but lagged behind demand for the second consecutive year (see Nickel chapter). A shortage of cathode and briquets caused prices to rise at the beginning of 2000. The monthly LME cash price for 99.8% pure nickel peaked at $10,280 per metric ton in March and then gradually declined during the remainder of the year to finish at $7,314 per metric ton. The gradual price decline was attributed to the buildup of recessionary forces in the United States and parts of East Asia. Prices for austenitic scrap in Pittsburgh closely tracked the LME price and also gradually declined during the last half of the year.

Russia and the United States continued to be the largest exporters of stainless steel scrap. The huge influx into Western Europe of Russian stainless steel scrap and nickel alloy scrap, which began in 1995, slackened in the first half of 1999 after the Russian Government imposed a new tariff on scrap metal exports. Nickel and six other scrap metals were subject to the 20% export tariff (Reuters Ltd., 2000a, b). In November 1999, the tariff was raised to 30% (Interfax International Ltd., 2000a). Because of the tariff and low prices for cathode at the time, Russian exports of stainless steel scrap fell 9% between 1998 and 1999, dropping from 343,000 t (gross weight) to 313,000 t (International Nickel Study Group, 2001b, p. 79). Russian scrap exports recovered in the second half of 1999 in response to higher nickel prices and continued to rise throughout 2000. (See Figure 1.) At yearend 2000, nickel in scrap was being quoted in Europe at 84% of the LME cash price. Discounts in the United States were greater than those in Europe, with U.S. scrap prices equivalent to about 77% of LME nickel values. Discounts began 2000 on both continents at 88%.

The Russian Government extended its 5% export tariff on refined nickel into 2000 and later raised it to 10%. The new tariffs and regulations left nonferrous scrap brokers in a more precarious position than the primary producers. In March 2000, the Russian Ministry of Economics proposed raising the 30% tariff on scrap to 50%—to curb excessive exports (Interfax International Ltd., 2000b; Reuters Ltd., 2000a, b). Federation officials also were evaluating new procedures for levying value-added taxes on exports. The entire policy of levying tariffs on exports was debated in the Federal Council, the upper house of the Russian Parliament.

Inmetco converts a variety of nickel and chromium wastes at Ellwood City, PA, into a remelt alloy suitable for stainless steelmaking. The Ellwood City operation was set up in 1978 to reclaim chromium and nickel from emission control dusts, swarf, grindings, mill scale, and other wastes generated by the stainless steel industry. Over the past 22 years, Inmetco has made a number of improvements to its Pennsylvania facility and now also processes nickel- and/or chromium-bearing filter cakes, plating solutions and sludges, catalysts, refractory brick, and spent batteries.

ELG Haniel GmbH handled about 1.2 Mt of stainless steel scrap worldwide in 1999, up 9% from that of 1998. About 790,000 t was sold to steelworks in Germany and other EU member countries. The company moved the scrap processing facilities of Jewometaal, its Dutch subsidiary, to a new location in the Port of Rotterdam. Jewometaal spent Eur 8 million, or about $7.7 million, on the new recycling and transshipment facilities (ELG Haniel GmbH, 2000, p. 32-33).

U.S. industry recycles a broad spectrum of other nickel-bearing materials in addition to stainless steel. Copper-nickel alloy scrap and aluminum scrap accounted for about 10% of the

nickel reclaimed in 2000. Scrap in this category comes from a myriad of sources and includes cupronickel (a series of copper alloys containing 2% to 45% Ni), the Monels (a group of alloys typically containing 65% Ni and 32% Cu), nickel-silver (a misnomer for a series of copper-zinc-nickel alloys), and nickel-aluminum bronze. Cupronickel is stronger and more resistant to oxidation at high temperatures than pure copper, making it desirable for saltwater piping and heat exchanger tubes. Nickel-silver—a white brass—is used for rivets, screws, camera parts, and optical equipment. The aerospace industry uses 2218, 2618, 4032, 8280 and several other wrought aluminum alloys that contain 0.2% to 2.3% nickel.

The remaining 8% of reclaimed nickel came from pure nickel scrap and nickel-base alloy scrap. Superalloy producers and downstream fabricators of turbine engines and chemical processing equipment generate a large part of this material—some of which is sent to scrap processors for salvaging and cleaning and later returned to the producers for remelting. However, because of the stringent specifications for INCONEL 718, WASPALOY, and similar aerospace-grade superalloys, much of the superalloy scrap is not suitable for direct recycling and is sold to stainless steel producers, steel foundries, or specialty alloy casting companies. Significant amounts of superalloy scrap are intentionally generated during the forging and machining of turbine parts for aircraft engines. As little as 1 out of 7 kg of superalloy may end up in a finished turbine part (Lane, 1998). Superalloy scrap is an important source of revenue for most aerospace machine shops. Proper segregation of turnings and grindings, on-site recovery of cutting fluids, and timely shipping of the scrap can make the difference between profitability and bankruptcy for a small- to medium-size machine shop. Inclusion of a pea-size piece of a lead, bismuth, or tungsten alloy can put an entire truckload of superalloy scrap out of specification. Aircraft engine repair facilities are an important source of obsolete superalloy scrap.

Demand for superalloy scrap reached record levels in 2000. Three factors contributed to the tightness of supply. First, manufacturing of land-based gas turbines increased dramatically as power companies rushed to meet growing demand for electrical power, especially on the West Coast of the United States. Second, orders for new jet aircraft engines and other aerospace components picked up after a 2-year downturn. Third, several processors of superalloy scrap were operating at maximum capacity. Low prices for primary nickel in 1998 and 1999 had discouraged the scrap industry from adding new processing capacity in 2000. A major problem was inadequate capacity to process turnings from machine shops. Turnings are one of the larger sources of superalloy scrap, but require considerable processing. Scrap processors must crush, sample, clean, densify, and package the turnings before they can be shipped to the buyer (Newman, 2001).

To help relieve the tightness in the superalloy scrap market, Keywell LLC set up a new processing facility in Los Angeles, CA, in early 2000. The Los Angeles facility became operational in the second half of 2000 and has begun consolidating shipments for forwarding to Keywell's Vac Air Alloys Division at Frewsburg, NY. The Frewsburg facility reportedly is the largest processor of vacuum-grade superalloy and titanium scrap in the world. In March, Keywell also opened a new facility in Fairless Hills, PA, to process stainless steel scrap in bulk.

Superalloy scrap processors now have to compete with stainless steel blenders and nickel-cobalt refineries for the scrap. The ongoing expansion of the Airbus consortium is expected to increase superalloy arisings in Western Europe. To date, superalloy melters have shied away from Russian aerospace scrap. Traditional Russian aerospace grades are difficult to blend with Western alloys because of differences in chemical composition. These problems may disappear as Russia begins producing more Western-equivalent grades of superalloys.

The U.S. collection and recycling program for NiCd and nickel-metal hydride (NiMH) batteries is in a period of rapid expansion. Federal legislation passed in 1996 has helped spur the program. The program is administered by Rechargeable Battery Recycling Corp. (RBRC), a nonprofit public service corporation funded by more than 285 manufacturers and marketers of portable rechargeable batteries and battery-operated products (Millard, 1999). The program is primarily designed to recycle the more than 75 million small, sealed, rechargeable NiCd batteries sold annually to U.S. and Canadian businesses and consumers for use in cordless products. RBRC licensees now account for four out of five NiCd sales in North America. Almost 25,000 retail outlets or community collection sites in the United States accept spent NiCd batteries. Some 4,500 collection sites in Canada also participate in the RBRC program. The bulk of the collected batteries are sent to Inmetco for reclamation.

In Western Europe, the portable battery market grew from 2.8 billion units in 1985 to almost 4.9 billion units in 1995, an increase of 70%. This increase has led to renewed concerns in the EU about the inclusion of NiCd batteries in municipal waste going to landfills or incinerators. About 62% of the municipal waste in the EU is currently landfilled; another 19% is incinerated. In March 2001, the European Commission drafted a directive that calls for the phase out of cadmium in portable batteries by January 1, 2008. Special exemptions were proposed for batteries used in medical devices, emergency equipment, and special scientific instrumentation. The proposed directive also would establish a minimum recycling target of 55% for all collected batteries. More costly NiMH and lithium-ion batteries would be substituted for the NiCds. Some 13,000 t of portable NiCd batteries averaging 15% cadmium (Cd) and 3,500 to 4,000 t of industrial NiCd batteries averaging 6% Cd are marketed annually in the EU. Industry studies show that only 11% of the portable NiCd batteries were being reclaimed compared with 53% of the industrial batteries (Commission of the European Communities, 2001).

A proposal by the U.S. Department of Energy (DOE) to decontaminate 6,000 t of radioactively contaminated nickel was opposed by a large part of the metals industry. The House Committee on Commerce also expressed its concerns to DOE. The Metals Industry Recycling Coalition has taken the position that no metal originating from Nuclear Regulatory Commission (NRC)-licensed fuel cycle and DOE-operated facilities should be released for unrestricted recycling or reuse even if the levels of radioactivity are within "safe" levels specified by the NRC. The Steel Manufacturers Association took legal action to delay an NRC rule that would have allowed the material to be decontaminated and recycled back to the public. Other coalition members included the Specialty Steel Industry of North America, the American Iron and Steel Institute, the Nickel Development Institute, and the Copper and Brass Fabricators

Council (Kelly, 1999).

Platinum-Group Metals[18]

Despite their limited availability, platinum-group metals (PGM), and chemical compounds containing them, are widely used as catalysts in the chemical and petroleum industries as well as used in electrical conductors, extrusion devices, dental and medical prostheses, and jewelry. Since 1998, platinum has been used in the manufacture of computer hard disks. Moreover, since the beginning of the 1975 model year, new automobiles sold in the United States have been equipped with PGM-based (primarily platinum) catalytic converters to remove polluting substances from engine exhausts.

For most PGM applications, the actual loss during use of the metal is small, and hence the ability to recover the metal efficiently contributes greatly to the economics of PGM use. Typical sources of PGM for secondary refining include catalysts, electronic scrap, jewelry, and used equipment, e.g., from the glass industry. Spent automotive catalysts have emerged as the leading source of secondary PGM. The United States has the world's most developed network for recycling spent autocatalysts; most domestic scrap yards systematically remove catalytic converters from scrapped vehicles. Although smaller vehicle dismantlers have considered it uneconomical to collect the catalysts, the rise in PGM prices prompted many of them to begin removing catalytic converters for the first time in 2000. This development led to an increase in the amount of platinum recovered—from about 9,800 kg in 1999 to about 10,900 kg in 2000. In recent years, palladium catalysts have become more widely used in catalytic converters for motor vehicles. An estimated 4,700 kg of palladium was recovered in 2000.

Selenium[19]

Most selenium, except that applied to the surfaces of the photoreceptor drums in plain paper copiers, is dissipated as process waste or is eventually sent to a landfill as a minor constituent of a used product. The small quantities that are added to glass as a decolorant and to ferrous and nonferrous metal alloys to improve metalworking properties are not recovered in the recycling of those materials and are probably volatilized during remelting. Selenium rectifiers, once a major source of old scrap, generally have been replaced by silicon rectifiers. Additionally, current high processing costs have made it uneconomical to recover selenium from the scrapped rectifiers that are available.

In 2000, no secondary selenium was recovered in the United States. Wornout photoreceptor drums and scrap generated in the manufacture of new drums were exported for the recovery of the selenium content. An estimated 50 t of secondary selenium was imported; this was about 10% of all selenium imports. Practically all the selenium used in photoreceptor drums is recovered through very efficient recycling programs (Hoffman and King, 1997, p. 704). Secondary selenium was recovered in Canada, Europe, Japan, and the Philippines. The photocopier market for selenium, still the main feed source for secondary selenium, continued its decline owing to competition from other technologies, mainly organic photoreceptors.

Hydromet Environmental Recovery Ltd. will accept waste material for the recovery of selenium and tin at its new plant scheduled to open during 2001 in Newman, IL. The plant expects to process selenium materials from the copper refining and photocopy industries (American Metal Market, 2000b).

Silver[20]

About 1,680 t of silver, valued at $270 million, was recovered from scrap in 2000. Photographic scrap was estimated to have generated 1,300 t of silver; the largest part was recovered from spent fixer solution, x ray and graphic arts wastes, and a small quantity directly from color film wastes. The remainder was recovered from jewelers' sweepings, spent catalysts, electronic scrap, and other heterogeneous silver bearing materials. Recovered silver accounted for about one-fourth of industrial demand in 2000.

Tantalum[21]

Tantalum is ductile, easily fabricated, highly resistant to corrosion by acids, and a good conductor of heat and electricity and has a high melting point. The major use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. More than 60% of total tantalum consumed is in the electronics industry. Major end uses for tantalum capacitors include portable telephones, pagers, personal computers, and automotive electronics. Alloyed with other metals, tantalum is also used in making carbide tools for metalworking equipment and in the production of superalloys for jet engine components. Substitutes such as aluminum, rhenium, titanium, tungsten, and zirconium, can be used in place of tantalum but are usually used at either a performance or economic penalty.

In 2000, U.S. apparent consumption of tantalum totaled about 650 t, with consumed scrap (from various sources) accounting for an estimated 20% of the total. Recycling of tantalum, mostly from new scrap, takes place largely within the processing and end-product industries. In addition, quantities of tantalum are recycled in the form of used tantalum-bearing cutting tools and high-temperature alloy melting scrap. Tantalum recycled from finished electronic components (old scrap) is very small and not yet fully developed. However, new scrap materials reclaimed at manufacturing plants that produce tantalum-related electronic components are a major source of tantalum supply and are delivered back to tantalum processors for recycling (Cunningham, 1985, 2001b; Tantalum-Niobium International Study Center, 1996).

Tin[22]

In 2000, about 30% of the domestic apparent supply of tin metal was recovered from scrap (table 1). Old tin scrap is collected at hundreds of domestic scrap yards, five detinning

Digitized by Google

plants, and most municipal collection-recycling centers. New tin scrap is generated mainly in the tin mills of six steel plants, scores of canmaking facilities, numerous brass and bronze plants, and many soldermaking operations. Most tin-scrap-processing facilities are close to the tin-using industries and to densely populated markets in the Midwest and the Northeast.

Detinning facilities are unique to the tin scrap industry in that no other major metal industry has numerous large-scale plants to remove plated metal. Detinning operations are performed on new tinplate scrap from tin mills or canmaking plants and on old tinplate scrap in the form of used tin cans. For most of the past century, the detinning process has been the only technique in the secondary tin industry by which free tin metal returns to the marketplace. The bulk of the secondary tin industry works with the various alloy forms of tin (brass, bronze, solder, etc.); the tin is recycled within its own product-line industries and thus reappears in regenerated alloys.

The Steel Recycling Institute (SRI) continued to promote the recycling of used tin cans, which has become an important raw material for the nation's steel industry during the past 15 years. SRI announced that the domestic steel can recycling rate had remained about the same in 2000 as in 1999 at 58%, compared with 56% in 1998, and 15% in 1988 (Steel Recycling Institute, 2001).

Tin scrap prices are rarely published, but generally approximate the prices for primary tin metal.

Titanium[23]

Titanium scrap is primarily used as an alternative to titanium sponge in the production of titanium ingot. Common forms of titanium scrap include turnings and bulk weldables (bars, billet cutoffs, plate trimmings, etc.). Titanium scrap is generated during the melting, forging, casting, and fabrication of titanium components. "New scrap" is generated during the production and fabrication of titanium components, while "old scrap" is recovered from used components (old aircraft parts, heat exchangers, submarine hulls, etc.).

Currently, over one-half of the titanium feedstock for ingot production is derived from scrap. Scrap is recycled into titanium ingot with or without virgin metal by using either vacuum-arc-reduction or cold-hearth melting practices. Titanium ingot producers in France, Germany, Japan, Russia, the United Kingdom, and the United States lead the recycling of titanium scrap. In the United States, titanium ingot producers (recyclers) included Allegheny Technologies Inc., Howmet International, Lawrence Aviation Industries Inc., RMI Titanium Co., and Titanium Metals Corp. Numerous companies were involved in the generation, segregation, and processing of scrap for recycling.

In 2000, U.S. production of titanium ingot decreased 3% compared with that of 1999. Scrap supplied about 50% of the titanium required for ingot production, somewhat less than the 55% supplied in 1999. Although no data are available as to the percentage breakdown of sources of titanium scrap, less than 2% of titanium ingot production is estimated to be derived from old scrap.

Although consumption of titanium metal by commercial aircraft producers remained relatively high from an historical perspective, recycling of titanium scrap decreased by about 9% compared with that of 1999. While imports of titanium scrap increased 9% compared with those of 1999, exports decreased 38%. In contrast to 1999, the United States was a net exporter of titanium scrap in 2000, with exports exceeding imports by 2,490 t.

In addition to that recycled by ingot producers, titanium scrap is consumed by the steel and nonferrous alloy industries. It should be noted that imports and exports of titanium scrap include material to be recycled back into titanium components and that consumed by steel and nonferrous alloys.

Consumption by the steel industry is largely associated with the production of stainless steels and is used for deoxidation, grain-size control, and carbon and nitrogen control and stabilization. In steelmaking, titanium is introduced as a ladle addition normally in the form of ferrotitanium because ferrotitanium has a lower melting point and has a higher density than scrap. Ferrotitanium is produced from titanium and steel scrap by induction melting.

World ferrotitanium production capacity is estimated to be 64,000 t, led by, in descending capacity order, the United Kingdom, Russia, Japan, and the United States. In 2000, there were three domestic producers of ferrotitanium: Global Titanium, Inc., Detroit MI; Galt Alloys Inc., North Canton, OH; and ShieldAlloy Inc., Newfield, NJ. In addition to domestic producers, numerous companies are involved in the import and trade of ferrotitanium.

In the nonferrous metals industry, titanium scrap is primarily consumed to produce aluminum-titanium master alloys for the aluminum industry. When used in aluminum alloys, titanium improves casting and reduces cracking.

Owing to a moderate drop in demand, prices for unprocessed titanium scrap turnings (Ti-6AL-4V) decreased from about $1.10 per pound at yearend 1999 to $0.78 per pound at yearend 2000. Yearend prices for ferrotitanium prices decreased from about $2.40 per pound in 1999 to $1.59 per pound in 2000.

Future consumption of titanium scrap is largely dependent on demand for titanium metal products by the aerospace industry. Over the next decade, titanium demand by the aerospace industry is expected to exceed 5%; however, growth in the aerospace industry is cyclical. Growth in the consumption of ultra low carbon steels for automotive applications and appliances is expected to increase demand for ferrotitanium. Given the long-term growth trend for ferrotitanium imports, imports are expected to meet much of the future domestic demand for ferrotitanium.

Tungsten[24]

In 2000, an estimated 25% to 30% of world tungsten supply was from recycled materials (Maby, 1999, p. 4). Tungsten-bearing scrap originates during manufacture and/or after use in the following applications: cemented carbides used for cutting and wear-resistant applications; mill products made from metal powder, such as filaments and electrodes for lamps and heavy metal alloys; and alloys, such as tool steels, high-speed steels, and superalloys. Depending on the type and quality of the scrap,

[23]Prepared by Joseph Gambogi (703) 648-7718; Fax (703) 648-7722.

it can be recycled by the industry sector that generated it, used as a source of tungsten by another consuming industry, or used as a substitute for tungsten concentrate by tungsten processors (Smith, 1994, p. 4-14).

Cemented carbide scrap is recycled by several processes. Some of these processes result in tungsten carbide powder combined with cobalt, which can be used to make new cemented carbide parts. In other processes, the cobalt is recovered separately, and the tungsten is converted to the intermediate product ammonium paratungstate from which tungsten carbide powder, chemicals, or metal powder can be produced. Tungsten metal scrap from the manufacture of mill products is used to make cast carbides, ferrotungsten, superalloys, and tool steel. It can also be processed chemically to produce ammonium paratungstate. Most heavy metal alloy manufacturing scrap is recycled as home scrap to a prealloyed powder, but it can also be chemically converted to ammonium paratungstate or used to produce tool steel (Kieffer, 1982, p. 102-107). Steel scrap and superalloy scrap are recycled by the steel and superalloys industries, respectively.

In 2000, scrap consumption reported by U.S. tungsten processors and consumers was 5,120 t of contained tungsten, an increase of 3% from the 4,980 t (revised) consumed in 1999. The United States imported 993 t of tungsten contained in waste and scrap, valued at $6.2 million, 31% less than the tungsten content of waste and scrap imports in 1999. Five countries supplied 70% of these imports—China, 25%; the Republic of Korea and Russia, 15% each; Germany, 8%; and Japan, 7%. U.S. exports of tungsten waste and scrap were an estimated 827 t of contained tungsten valued at $4.4 million, which was approximately equal to the estimated tungsten content of waste and scrap exports in 1999. The leading destinations for these exports were Germany, 48%; Taiwan, 10%; China, 7%; Canada; 6%; and Belgium, 5%.

Vanadium[25]

Vanadium is used primarily as an alloying element. Very small quantities of vanadium, often less than 1%, are alloyed with other metals to produce various ferrous and nonferrous alloys. Owing to the relatively small amount of vanadium involved, these alloys in general do not lend themselves to recycling for vanadium recovery. Vanadium is also used as a catalyst. It is estimated that catalyst consumption accounts for less than 1% of the total U.S. vanadium consumption. However, processing spent vanadium catalysts accounts for the only significant source of refined secondary vanadium. Three plants in Arkansas, Louisiana, and Texas accounted for most of the recycled vanadium catalyst. Any new scrap generated in either the production of alloys or catalysts is likely reused internally.

Zinc[26]

In 2000, about 30% of world's zinc production was produced from secondary materials—brass, die casting scrap, flue dust, galvanizing residues, zinc sheet, etc. In the United States, more than one-fourth of the 1.61 Mt consumed by domestic industries is secondary zinc. More than three-quarters of recycled zinc was derived from new scrap generated mainly in galvanizing and die casting plants and brass mills. The remaining one-quarter was obtained from brass products, flue dust, old die casts, and old rolled zinc articles. Recycled zinc was used by 3 primary smelters and 12 large and medium (more than 1,000 t/yr) sized secondary smelters primarily for production of zinc chemicals, mainly oxide, and zinc metal, including alloys. In addition, there is a changing number of smaller companies that usually produce zinc chemicals. IMCO Recycling Inc., Midwest Zinc Corp., and Zinc Corp. of America are the largest U.S. recyclers of zinc.

Because of wide differences in the character and zinc content of scrap, the recycling processes of zinc-bearing scrap vary widely. Clean new scrap, mainly brass, rolled zinc clippings, and rejected die castings, usually requires only remelting. In the case of mixed nonferrous shredded metal scrap, zinc is separated from other materials by hand or magnetic separation. Most of the zinc recovered from EAF dust, produced during remelting of galvanized steel scrap, is recovered in rotary kilns by using the Waelz process. Because the most common use of zinc is for galvanizing, the latest research is aimed mainly at stripping zinc from galvanized steel scrap before remelting.

In 2000, trade in zinc scrap was small—about 2% of total domestic consumption. Nearly 93% of imported zinc scrap was supplied by Canada, and the major destination of U.S. exports was Taiwan (51%). Prices for scrap varied according to quality, presence of other components, geographic location, and environmental difficulties in handling, transporting, or treating. The price for a ton of zinc metal contained in scrap was about three-fourths of the LME price for refined zinc metal.

Zirconium[27]

Zirconium scrap comprises about one-fourth to one-third of the feedstock for ingot production. New scrap is generated during the melting, forging, rolling, casting, and fabrication of zirconium components. In addition, some obsolete or old scrap is recycled from dismantled process equipment, vessels, heat exchangers, etc. Although no data are available as to the percentage breakdown of sources of scrap, it is estimated that less than 2% of ingot production is derived from old scrap. Prior to melting, scrap must be analyzed, classified, and processed to remove impurities. Several companies have proprietary processes to accomplish this task. Scrap is initially melted without virgin metal by the two domestic ingot producers, Wah Chang, a subsidiary of Allegheny-Teledyne Corp., Albany, OR, and Western Zirconium, a subsidiary of Westinghouse Electric Co., Ogden, UT, using vacuum-arc-reduction melting practices.

TABLE 1--Continued
SALIENT U.S. RECYCLING STATISTICS FOR SELECTED METALS 1/

e/ Estimated. r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Scrap that results from the manufacturing process, including metal and alloy production. New scrap of aluminum, copper, lead, tin, and zinc excludes home scrap. Home scrap is scrap generated and recycled in the metal producing plant.
3/ Scrap that results from consumer products.
4/ Metal recovered from new plus old scrap.
5/ Apparent supply is production plus net imports plus stock changes. Production is primary production plus recycled metal. Net imports are imports minus exports. Apparent supply is calculated on a contained weight basis.
6/ Same as apparent supply defined in footnote 5 above but calculated on a monetary value basis.
7/ Scrap quantity is the calculated metallic recovery from purchased new and old aluminum-base scrap, estimated for full industry coverage. Monetary value is estimated based on average U.S. market price for primary aluminum metal ingot.
8/ Chromium scrap includes estimated chromium content of stainless steel scrap receipts (reported by the iron and steel and pig iron industries) where chromium content was estimated to be 17%. Trade includes reported or estimated chromium content of chromite ore, ferrochromium, chromium metal and scrap, and a variety of chromium-containing chemicals. Stocks include estimated chromium content of reported and estimated producer, consumer, and Government stocks. Recycled value calculated from quantity using the average annual import value of high-carbon ferrochromium. Apparent supply value calculated from quantity using average annual trade value.
9/ Includes copper recovered from unalloyed and alloyed copper-base scrap, as refined copper or in alloy forms, as well as copper recovered from aluminum-, nickel-, and zinc-base scrap. Monetary value based on annual average refined copper prices.
10/ Iron production measured as shipments of iron and steel products plus castings corrected for imported ingots and blooms. Secondary production measured as reported consumption. Apparent supply includes production of raw steel. Monetary value based on U.S. annual average composite price for No. 1 heavy melting steel calculated from prices published in American Metal Market.
11/ Lead processors are segregated by primary and secondary producers. This segregation permits inclusion of stock changes for secondary producers. Monetary value of scrap and apparent supply estimated based upon average quoted price of common lead. Excludes copper-based scrap.
12/ Includes magnesium content of aluminum-base scrap. Monetary value based on the annual average Platt's Metals Week's U.S. spot Western price.
13/ Nickel statistics were derived from the following:

Canvass data
- •Reported nickel content of products made from reclaimed stainless steel dust, spent nickel-cadmium batteries, plating solutions, etc.
- •Estimated nickel content of reported net receipts of alloy and stainless steel scrap.
- •Reported nickel content of recovered copper-base scrap.
- •Reported nickel content of obsolete and prompt purchased nickel-base scrap.
- •Estimated nickel content of various types of reported obsolete and prompt aluminum scrap.

Trade data
- •Reported nickel content of International Nickel Study Group (INSG) Class I primary products, including cathode, pellets, briquets, powder, and flake.
- •Reported or estimated nickel content of INSG Class II primary products, including ferronickel, metallurgical-grade nickel oxide, and a variety of nickel-containing chemicals.
- •Estimated nickel content of secondary products, including nickel waste and scrap and stainless steel scrap.

Stock data
- •Reported or estimated nickel content of all scrap stocks, except copper.
- •Reported nickel content of primary products held by world producers in U.S. warehouses.
- •Reported nickel content of primary products held by U.S. consumers.
- •Reported nickel content of U.S. Government stocks.

Monetary value based on annual average cash price for cathode, as reported by the London Metal Exchange.
14/ Monetary value based on Platt's Metals Week Composite price for tin.
15/ 1998 to 2000 new scrap data include data unavailable for 1996 and 1997.
16/ Percentage recycled based on titanium scrap consumed divided by primary sponge and scrap consumption.
17/ Monetary value based on annual average Platt's Metal Week metal price for North American special high-grade zinc.

RHENIUM

By John W. Blossom

Domestic survey data and tables were prepared by Jo-Ann S. Sterling, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

In the past decade, the two most important uses of rhenium have been in platinum-rhenium catalysts and high-temperature superalloys. Platinum-rhenium catalysts are used to produce lead-free, high-octane gasoline. Superalloys are used for turbine engine components. Other applications of rhenium, primarily as tungsten-rhenium and molybdenum-rhenium alloys, are more diverse; these included thermocouples, heating elements, temperature controls, flashbulbs, vacuum tubes, x-ray tubes and targets, metallic coatings, and electrical contact points. Research by industry continued on the recovery of rhenium from ore and concentrate and the development of new catalysts and alloys.

In the United States, rhenium is a byproduct of molybdenite recovered as a byproduct of porphyry copper ore from six operating porphyry copper-molybdenum-rhenium mines in the Western States. Domestic mine production data for rhenium (table 1) were derived by the U.S. Geological Survey from reported molybdenum production at the mines. Domestic demand for rhenium metal and other rhenium products was met principally by imports, but also from domestic recovery and stocks.

Compared with that of 1999, 2000 rhenium consumption decreased by about 1.5%; imports of metal for consumption decreased by 16% and imports of ammonium perrhenate increased by 171% (table 1). The average prices for metal powder and ammonium perrhenate were $1,009 and $514 per kilogram, respectively.

Consumption

Rhenium is used in petroleum-reforming catalysts for the production of high-octane hydrocarbons, which are used in the production of lead-free gasoline. Bimetallic platinum-rhenium catalysts have replaced many of the monometallic catalysts. Rhenium catalysts tolerate greater amounts of carbon formation in making gasoline and make it possible to operate the production process at lower pressures and higher temperatures, which leads to improved yields (production per unit of catalyst used) and higher octane ratings. In 2000, catalytic uses comprised about 20% of rhenium consumption reported in table 1. Platinum-rhenium catalysts also were used in the production of benzene, toluene, and xylenes, although this use was small compared with that of gasoline production.

A significant property of rhenium is its ability to alloy with molybdenum and tungsten. Molybdenum alloys containing about 50-weight-percent rhenium have greater ductility and can be fabricated by either warm or cold working. Unlike other molybdenum alloys, this type of alloy is ductile at temperatures above 196° C and can be welded. Alloys of tungsten with 24-weight-percent rhenium have improved ductility and have lower ductile-to-brittle transition temperatures than pure tungsten. Rhenium improves the strength properties of nickel alloys at high temperatures (1,000° C). In 2000, metallurgical uses comprised about 75% of rhenium consumption. Other uses for these alloys, which collectively represented only 5% of total consumption, were in thermocouples, temperature controls, heating elements, ionization gauges, mass spectrographs, electron tubes and targets, electrical contacts, metallic coatings, vacuum tubes, crucibles, electromagnets, and semiconductors.

Foreign Trade

Imports for consumption of rhenium metal are listed in tables 1 and 2, and those of ammonium perrhenate are listed in tables 1 and 3. World production of rhenium in ore was estimated to be 28 metric tons (t); the quantity of rhenium recovered is

Rhenium in the 20th Century

Following the discovery of rhenium in 1925, the usual investigative work to isolate sufficient quantities, determine its properties, and locate adequate sources began. Rhenium remained little more than a curiosity until the latter half of the century.

In 1956, after several years of development, Kennecott Copper Corp. began producing rhenium at Washington, PA, where Molybdenum Corp. of America roasted Kennecott's Bingham Canyon Mine molybdenite concentrates. No more than 4,600 kilograms of rhenium was produced in the Western World between 1942 and 1965, with most used in research and development. Industrial use was small, mostly metallurgical, in high temperature thermocouples and some electronic uses.

In the late 1960s, the use of rhenium in catalysts began when both Chevron, Inc., and UOP, Inc., developed the bimetallic platinum-rhenium reforming catalysts. The first charge of catalyst was installed in Chevron's El Paso, TX, refinery. The price of rhenium escalated to $1,870 per kilogram in 1969 and to a high of $3,080 per kilogram in 1971. These high prices of 1971 and 1972 stimulated competition with rhenium in the form of indium and germanium catalysts. Rhenium prices have fluctuated widely since that time.

In 2000, metallurgical applications returned to being the major use because of usage by the turbine engine industry. The estimated U.S. consumption of rhenium in 2000 was about 32,000 kilograms of metal.

Digitized by Google

estimated to have been about 25 t, because not all concentrates were processed to recover the rhenium values. Rhenium was recovered from some byproduct molybdenite concentrates from porphyry copper deposits in Canada, Chile, China, Iran, Kazakhstan, Peru, Russia, and the United States. Rhenium metal and compounds were produced in Chile, France, Germany, Russia, the United Kingdom, and the United States.

World Review

World reserves of rhenium are contained primarily in molybdenite in porphyry copper deposits. U.S. reserves of rhenium are concentrated in Arizona, New Mexico, and Utah. Chilean reserves are found primarily at four large porphyry copper mines and in lesser deposits in the northern one-half of the country. In Peru, reserves are concentrated primarily in the Toquepala open pit porphyry copper mine and in about 12 other deposits in the rest of the country.

Other world reserves are in several porphyry copper deposits and sedimentary copper deposits in Armenia, northwestern China, Russia, and Uzbekistan and in sedimentary copper-cobalt deposits in the Congo (Kinshasa).

Technology Development

The feasibility of introducing rhenium as an in situ diffusion barrier to reduce the loss of aluminum from an aluminum diffusion barrier coating has been investigated by researchers at Hokkaido University, Sapporo, Japan. The results were reported at the NACE Corrosion 2001 conference in Houston, TX. Rhenium is added to superalloys to improve creep resistance. In addition, slow diffusion of rhenium has been shown to be responsible for slower coarsening kinetics in single crystals. In the study, a nickel-base single crystal superalloy containing rhenium was aluminum-diffusion treated, then oxidized in air at 1,373 K for up to 2.54 megaseconds under thermal cycling and isothermal conditions. The treatment was carried out in a mixture of FeAl and Al_2O_3 powder. It resulted in a triplex layer structure in the sequence beta NiAl/Re rich layer/Al diffusion zone (Narita, 2001).

Outlook

In the next 5 years, demand for rhenium metal was expected to follow the demand for turbine engines and petroleum. For the long term (10 to 20 years), recycling of rhenium-bearing waste and scrap was expected to increase. Identified U.S. resources are estimated to be about 7,000 t, and identified rest-of-world resources are estimated to be about 10,000 t.

SALT

By Dennis S. Kostick

Domestic survey data and tables were prepared by Jeff Milanovich, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Salt, also known as sodium chloride, is composed of the elements sodium and chlorine. Sodium is a silver-colored metal, which is so unstable that it reacts violently in the presence of water, and chlorine is a greenish-colored gas that is dangerous and lethal. Yet the combination of these two elements forms sodium chloride, which is a white-colored compound essential to life itself. Virtually every person in the world has some direct or indirect contact with salt daily. People routinely add salt to their food as a flavor enhancer or apply rock salt to walkways to remove ice in the winter. Salt is used as feedstock for chlorine and caustic soda manufacture; these two inorganic chemicals are used to make many consumer-related end-use products, such as polyvinyl chloride (PVC), a plastic made from chlorine and paper-pulping chemicals manufactured from sodium hydroxide (caustic soda).

Production

U.S. production data for salt are developed by the U.S. Geological Survey (USGS) from an annual voluntary survey of U.S. salt-producing sites and company operations. The four types of salt that are surveyed are classified according to the method of recovery: rock salt, from the surface or underground mining of halite deposits; solar salt, from the solar evaporation of seawater, landlocked bodies of saline water, or primary or byproduct brines; vacuum pan salt, from the mechanical evaporation of a purified brine feedstock; and brine, from the solution mining of underground halite deposits. Data for brine production and consumption represent the anhydrous salt content only and not the weight of the water.

The structure of the U.S. salt industry has changed throughout the years. In 1970, 50 companies operated 95 salt-producing plants in the United States. Market competition, energy and labor costs, less expensive imports, currency exchange rates, and an excess of production capacity (resulting in the downsizing of the industry through mergers and acquisitions) reduced the size of the industry to 32 companies and 69 plants by 2000. The information and data are fundamental resources for analysis both within and outside the Government. The salt data and information are needed by the public and private sectors to better understand minerals and materials use and the ultimate disposition of materials in the economy and in the environment and to develop public and private sector policies and practices that better utilize our mineral and material resources. Some of the clients that use the salt data and information are financial institutions, State and Federal agencies, salt-consuming industries (e.g., agricultural, chemical, and food processing), educational institutions, and the general public.

Of the 32 companies to which a survey request was sent, all but 3 responded, representing 95% of the total production shown in this report. Data for nonrespondents were estimated based on their prior responses to previous annual surveys, the 2000 production estimate survey, or brine production capabilities for chloralkali manufacture based upon published chlorine production capacities [1.75 metric tons (t) of salt required per ton of chlorine capacity].

Total U.S. salt production increased by 2% in 2000 to 45.6 million metric tons (Mt) compared with that of 1999. According to the USGS canvass for 2000, 32 companies operated 69 salt-producing plants in 15 States. Of these, 9 companies and 17 plants produced more than 1 Mt each and accounted for 90% and 69%, respectively, of total U.S. production and 90% and 33%, respectively, of total value. Several companies and plants produced more than one type of salt. In 2000, 11 companies (14 operations) produced solar-evaporated salt; 6 companies (18 operations), vacuum pan salt; 11 companies (16 operations), rock salt; and 13 companies (32 operations), salt brine (tables 1-3).

Salt in the 20th Century

In 1900, the United States led the world as the largest salt-producing country, representing about 23% of total world output, followed by the United Kingdom, France, the German Empire, and Italy. Imports of fine salt decreased to 6% of domestic consumption in 1900 from 37% in 1880, because U.S. salt manufacturers steadily increased their production of table, dairy, and other special grades of salt. The major uses of salt at that time were food applications for humans and animals, leather tanning, and fish and meat preservation; however, use of salt as a chemical feedstock was beginning to increase with the development of the first soda ash plant in Syracuse, NY, in 1884 and the first electrolytic chlorine facility in Rumford, ME, in 1892. Although the first domestic automobile was not invented until 1896, the use of salt for road deicing would not begin until the 1930s.

In 2000, the top five salt-producing nations that collectively accounted for 55% of total world output, in descending order of quantity produced, were the United States, China, Germany, India, and Australia. The United States was the largest salt-producing nation, representing about 22% of total world output. The five leading States, in terms of total salt sold or used, were Louisiana, Texas, New York, Kansas, and Utah. The chemical industry, primarily the chlorine and caustic soda sectors, was the largest consumer of salt. Salt for domestic synthetic soda ash manufacture declined and eventually ceased in the last quarter of the 20th century because of environmental and energy issues and competition from natural soda ash. Salt for human consumption, which had been a major end use in the past century, declined to about 3% of total domestic consumption.

Digitized by Google

The five leading States in terms of total salt sold or used were Louisiana with 31%; Texas, 25%; New York, 13%; Kansas, 6%; and Utah, 5% (table 4). Other Eastern States (Alabama, Michigan, Ohio, Tennessee, and West Virginia) accounted for 17% of the domestic total salt sold or used. Other Western States (Arizona, California, Nevada, New Mexico, and Oklahoma) represented 3%.

Since the loss of the Retsof Mine in New York in 1995, progress continued on developing a new mine at Hampton Corners, NY. A group of investors formed American Rock Salt Co. LLC in 1997 and acquired the assets of the Retsof Mine, including a large salt stockpile, and mineral rights at Hampton Corners. On October 2, 1997, American Rock Salt shipped its first truckload of salt from the stockpile, while the company went forward with plans to sink a mineshaft to the underground salt formation. In late 1998, construction began on the mineshaft, and on November 18, 1999, salt was reached in the service shaft. On January 26, 2000, the first truckload of salt was delivered from the new mine. The mine was expected to reach its full capacity of 2.3 Mt by mid-2001 (American Rock Salt Co. LLC, 2001, Company biography and history, accessed May 22, 2001, via URL http://americanrocksalt.com).

In February, IMC Global Inc. announced it was interested in divesting its salt company IMC Salt Co. to refocus on its core crop-nutrient businesses. This divestment would include the rock salt operations in Louisiana and Canada, the vacuum pan salt plants in Kansas, and the solar salt facility in Utah (Chemical Market Reporter, 2000). In a cost-reduction effort, IMC closed its Hutchinson, KS, vacuum pan salt facility and increased vacuum pan salt production at its Lyons, KS, and Hersey, MI, plants (Bertram, 2000). Further capacity reductions in the domestic salt industry also occurred in late 1999 and into 2000, when Cargill Inc. closed its Redwood City, CA, solar salt plant, which had capacity of about 315,000 metric tons per year (t/yr).

Consumption

In 2000, apparent consumption (salt sold or used, plus imports, minus exports) was 51.6 Mt, whereas reported consumption (sales or use as reported by the salt companies including their imports and exports) was 54 Mt, which was an increase of 8% compared with that of 1999. Although these two measures of consumption are not necessarily supposed to be identical, they normally are similar. The 2.4-Mt difference between the two types of consumption for 2000 and 1999, however, can only be explained by stockpiling of imported salt by producers, distributors, and consumers during the year.

The direct and indirect uses of salt number about 14,000, according to industry sources. The USGS annually surveys 8 major categories comprising 29 end uses. The 2000 reported percentage distribution of salt by major end use was chemicals, 42%; ice control, 36%; distributors (grocery and other wholesalers and retailers, etc.), 7%; general industrial, 6%; agricultural, 4%; food processing, 3%; primary water treatment, 1%; and other uses combined with exports, 1%. Distributors represented a substantial share of salt sales by the salt industry; all of this salt is ultimately resold to many different end-users. For a more complete analysis of end-use markets, specific sectors of distribution in table 5 can be combined, such as agricultural and water treatment with agricultural and water conditioning distribution, respectively.

Aside from the different types of salt, there are various distinctions in the packaging and applications of salt. Salt for human consumption is packaged in different sized containers for several specialized purposes. Table salt may contain 0.01% potassium iodide as an additive, which provides a source of iodine that is essential to the oxidation processes in the body. Kosher salt, sea salt, condiment salt, and salt tablets are special varieties of salt.

Water conditioning and animal feed salt are made into 22.7-kilogram (50-pound) pressed blocks. Sulfur, iodine, trace elements, and vitamins are occasionally added to salt blocks to provide missing nutrients not found naturally in the diet of certain livestock. Salt is also compressed into pellets and used for water conditioning.

Chemical.—The largest consumer of salt, primarily salt brine, is the chemical industry. Within this industry, the chloralkali sector remains the major consumer of salt for manufacturing chlorine, coproduct sodium hydroxide, and synthetic soda ash. Since 1986, when the last synthetic soda ash plant closed because of high production costs and competition with less expensive natural soda ash, no synthetic soda ash has been manufactured in the United States; many countries, however, still produce synthetic soda ash and use vast quantities of salt brine as feedstock.

Salt is used as the primary raw material in chlorine manufacture because it is an inexpensive and widely available source of chlorine ions. For sodium hydroxide production, salt is the main source of the sodium ions. About 98% of the domestic chlorine and sodium hydroxide produced is obtained from the electrolysis of salt brine feedstock by using three-cell technologies. The types of cells and the percentages of chlorine manufactured by them are diaphragm, 78%; mercury, 14%; and membrane, 6%. The remaining 2% of chlorine and caustic soda production is recovered as a byproduct from magnesium and sodium metal manufacture.

It takes about 1.75 t of salt to make 1.0 t of chlorine and 1.1 t of coproduct caustic soda. The electrolytic process ionizes the sodium chloride compound and selectively allows the ions to migrate through special membranes. Chlorine gas forms at the anode, while sodium ions bond with water molecules at the cathode to form sodium hydroxide with hydrogen gas evolving.

Chlorine and caustic soda are considered to be the first generation of products made from salt. These two chemicals are further used to manufacture other materials, which are considered to be the second generation of products from salt. Although most salt brine is produced by the same companies that use it, many chloralkali manufacturers now purchase brine from independent brine supply companies. In certain cases, brine is produced by a chemical company that uses some of it and sells the excess to neighboring competitors. According to a survey of domestic salt-based chlorine facilities, about 48% of the salt used to manufacture chlorine was produced by manufacturing companies, and 31% was purchased brine. Solar salt, rock salt, and vacuum pan salt are also used to manufacture many chemicals (tables 5, 6).

In 2000, according to U.S. Census Bureau data, 12 Mt of chlorine and 11 Mt of sodium hydroxide (caustic soda or lye) were produced. Based on the industry average ratio of 1.75 t of salt required to produce 1.0 t of chlorine and 1.1 t of coproduct sodium hydroxide, the chlorine and caustic soda industry consumed about 21 Mt of salt for feedstock. Reported consumption of total domestic and imported salt for chlorine manufacture was 21.3 Mt (table 5). The difference between the calculated and reported quantities was the amount of salt not

Digitized by Google

reported to the USGS from imports or captive brine production of chloralkali producers.

Salt also is used as a feedstock in chemical establishments that make sodium chlorate (by the electrolysis of an acidified salt brine using hydrochloric acid adjusted to a pH of 6.5), metallic sodium (by the electrolysis of a molten salt mixture containing 33.2% sodium chloride and 66.8% calcium chloride, which is added to reduce the melting temperature of salt), and other downstream chemical operations. In powdered soaps and detergents, salt is used as a bulking agent and a coagulant for colloidal dispersion after saponification. In pharmaceuticals, salt is a chemical reagent and is used as the electrolyte in saline solutions. It also is used with sulfuric acid to produce sodium sulfate and hydrochloric acid. This subsector is relatively small, representing only 5% of domestic salt sales for the entire chemical sector and only 2% of total domestic salt consumption.

The consumption of salt for metallic sodium has declined during the past several years. Since the 1970s, the number of producers has decreased from three to one; Ethyl Corp. and RMI Titanium Corp. exited the market in 1985 and 1992, respectively, leaving E. I. du Pont de Nemours & Co., Inc., as the sole manufacturer of metallic sodium in the United States. In 1998, the domestic market was less than 30,000 t having decreased from about 126,000 t in 1978. The phasing out of tetraethyl lead and tetramethyl lead gasoline additives were the main reasons for the decline in consumption. In 1978, sodium usage in gasoline represented about 80% of the domestic market. Although there is no information about sodium consumption in 2000, the largest use of sodium in 1998 was for sodium borohydride production, which is the feedstock for sodium dithionite that is used as a reductive bleaching agent by the pulp and paper industry and accounted for about 38% of metallic sodium consumption. Sodium metal also is used to manufacture sodium azide, which is used in automotive airbags. Other promising uses of sodium metal are in the remediation of chemical weapons, pesticides, polychlorinated biphenyls, and chlorofluorocarbons.

Ice Control and Road Stabilization.—The second largest end use of salt is for highway deicing. The developer of the Fahrenheit temperature scale discovered that salt mixed with ice at a temperature below the freezing point of water creates a solution (brine) with a lower freezing point than water by itself. The brine forms below the surface of the ice and snow and prevents the water from freezing into ice and bonding with the road surface, thus causing the snow and ice to melt. Salt is an inexpensive, widely available, and effective ice control agent. It does, however, become less effective as the temperature decreases below about -9.5° C to -6.5° C (15° F to 20° F). At lower temperatures, more salt would have to be applied to maintain higher brine concentrations to provide the same degree of melting. Most winter snowstorms and ice storms occur when temperatures are between -4° C and 0° C (25° F and 32° F), the range in which salt is most effective. An anticaking agent, such as ferric ferrocyanide (Prussian Blue) or sodium ferrocyanide (Yellow Prussiate of Soda), is used to prevent the salt from agglomerating. Both additives are nontoxic and harmless to humans. In fact, sodium ferrocyanide is approved for use in food-grade salt by the U.S. Food and Drug Administration (Food and Nutrition Board, 1966).

In highway deicing, salt has been associated with corrosion of motor vehicles, bridge decks, unprotected steel structures, and reinforcement bar and wire used in road construction. Surface runoff, vehicle spraying, and windblown actions also affect roadside vegetation, soil, and local surface- and ground-water supplies. Although evidence of environmental loading of salt has been found during peak usage, the spring rains and thaws usually dilute the concentrations of sodium in the area where salt was applied.

Salt is also added to stabilize the soil and to provide firmness to the foundation on which highways are built. The salt acts to minimize the effects of shifting caused in the subsurface by changes in humidity and traffic load.

The quantity of salt consumed for road deicing each year is directly related to the severity or mildness of the winter weather conditions. Long-range forecasting of salt consumption in this application is extremely difficult because of the complexities in long-range forecasting of the weather. Meteorologists, however, are becoming more aware of the dynamics of certain weather phenomena that influence the climate in various parts of the world. One of these phenomena is El Niño, which is now believed to be the largest single weather influence on Earth. The mild winters of 1997 and 1998 were attributed to El Niño effects. In 1998, highway deicing salt sales were the lowest since about 1992, which also was an El Niño year (National Broadcast Co., 1998, El Niño facts, accessed July 15, 1998, at URL http://wxnet4.nbcr.com/elnino.html). The winters of 1999 and 2000 were colder and produced more precipitation that required more salt for road deicing as shown in the rock salt production statistics in tables 1 and 2 and the rock salt consumption data in tables 5 and 6.

Distributors.—A tremendous amount of salt is marketed through various distributors, some of which specialize in markets such as agricultural and water treatment services, two sectors where the salt companies sell directly as well (table 5). Distributor sales also include grocery wholesalers and/or retailers, institutional wholesalers, U.S. Government resale, and other wholesalers and retailers.

General Industrial.—The industrial uses of salt are diverse. They include, in descending order, oil and gas exploration, textiles and dyeing, other industrial applications, metal processing, pulp and paper, tanning and leather treatment, and rubber manufacture.

In oil and gas exploration, salt is an important component of drilling fluids in well drilling. It is used to flocculate and increase the density of the drilling fluid to overcome high down-well gas pressures. Whenever a drill hits a salt formation, salt is added to the drilling fluid to saturate the solution and to minimize the dissolution within the salt strata. Salt is also used to increase the set rate of concrete in cemented casings.

In textiles and dyeing, salt is used as a brine rinse to separate organic contaminants, to promote "salting out" of dyestuff precipitates, and to blend with concentrated dyes to standardize them. One of its main roles is to provide the positive ion charge to promote the absorption of negatively charged ions of dyes.

In metal processing, salt is used in concentrating uranium ore into uranium oxide (yellow cake). It is also used in processing aluminum, beryllium, copper, steel, and vanadium.

In the pulp and paper industry, salt is used to bleach wood pulp. It also is used to make sodium chlorate, which is added along with sulfuric acid and water to manufacture chlorine dioxide, an excellent oxygen-based bleaching chemical. The chlorine dioxide process, which originated in Germany after World War I, is becoming more popular because of environmental pressures to reduce or eliminate chlorinated

Digitized by Google

bleaching compounds.

In tanning and leather treatment, salt is added to animal hides to inhibit microbial activity on the underside of the hides and to replace some of the moisture in the hides. In rubber manufacture, salt is used to make buna, neoprene, and white types. Salt brine and sulfuric acid are used to coagulate an emulsified latex made from chlorinated butadiene.

Agricultural Industry.—Since prehistoric times, humankind has noticed that animals satisfied their salt hunger by locating salt springs, salt licks, or playa lake salt crusts. Barnyard and grazing livestock need supplementary salt rations to maintain proper nutrition. Veterinarians advocate adding loose salt in commercially mixed feeds or in block forms sold to farmers and ranchers because salt acts as an excellent carrier for trace elements not found in the vegetation consumed by grazing livestock; selenium, sulfur, and other essential elements are commonly added to salt licks, or salt blocks, for free-choice feeding.

Food Processing.—Every person uses some quantity of salt in their food. The salt is added to the food by the food processor or by the consumer through free choice, as a flavor enhancer, preservative, binder, fermentation-control additive, texture-control agent, and color developer. This major category is subdivided, in descending order of salt consumption, into meat packers, canning, other food processing, grain mill products, baking, and dairy.

In meat packing, salt is added to processed meats to promote color development in bacon, ham, and other processed meat products. As a preservative, salt inhibits the growth of bacteria, which would lead to spoilage of the product. Early pioneers stored their perishable food in salt barrels for protection and preservation. Salt acts as a binder in sausages to form a binding gel composed of meat, fat, and moisture. Salt also acts as a flavor enhancer and a tenderizer.

In the dairy industry, salt is added to cheese as a fermentation-control agent and as a color- and texture-control agent. The dairy subsector includes companies that manufacture creamery butter, natural and processed cheese, condensed and evaporated milk, ice cream, frozen desserts, and specialty dairy products.

In canning, salt is primarily added as a flavor enhancer and preservative. It also is used as a dehydrating agent, tenderizer, enzyme inhibitor, and carrier for other ingredients.

In baking, salt is added to control the rate of fermentation in bread dough. It also is used to strengthen the gluten (the elastic protein-water complex in certain doughs) and as a flavor enhancer, such as a topping on baked goods.

The food-processing category also contains grain mill products, which consist of milling flour and rice and manufacturing cereal breakfast food and blended or prepared flour.

In the "other food processing" category, salt is used mainly as a seasoning agent. Other food processing includes miscellaneous establishments that make food for human consumption (e.g., potato chips, pretzels) and for domestic pet consumption (e.g., cat and dog food).

Water Treatment.—Many areas of the United States have hard water, which contains excessive calcium and magnesium ions that contribute to the buildup of a scale or film of alkaline mineral deposits in household and industrial equipment. Commercial and residential water-softening units use salt to remove the ions causing the hardness. The sodium ions captured on a resin bed are exchanged for the calcium and magnesium ions. Periodically, the water-softening units must be recharged because the sodium ions become depleted. Salt is added and dissolved, and the brine replenishes the lost sodium ions.

Stocks

Because bulk salt is stored at many different locations, such as at the plants, warehouses, ports, and terminals, data on the quantity of salt stockpiled by the salt industry is not reliable enough to formulate accurate inventory totals; however, yearend stocks of producers were estimated to be 2 Mt, and consumer inventories also were estimated to be high. Most of these inventories were imported rock salt and solar salt. Many salt producers, States, municipalities, distributors, and road deicing contractors stockpiled additional quantities of salt in anticipation of adverse weather conditions. Deicing salt inventories were extremely large by yearend because the mild winter in the domestic snow belt did not require as much salt as had been stockpiled. For the reasons discussed above, salt stocks are assumed to be the difference between salt production and salt sold or used in calculating apparent consumption.

Transportation

Because the locations of the salt supplies are not often near consumers, transportation can become an important cost. Pumping salt brine through pipelines is an economic means of transportation but cannot be used for dry salt. Large bulk shipments of dry salt in ocean freighters or river barges are low in cost but are restricted in points of origin and consumption. River and lake movement of salt in winter is often severely curtailed because of frozen waterways. As salt is packaged, handled, and shipped in smaller units, the costs increase and are reflected in higher selling prices.

Transoceanic imports of salt have been increasing in some areas of the United States because they are less expensive with respect to transportation costs than that which could be purchased from domestic suppliers using rail transportation. Although shipping in larger vessels reduces shipping costs, transportation costs significantly add to the price of salt. In some cases, shipping costs are higher than the actual price of the salt. Another problem is that many ports are not deep enough to accommodate the larger ships.

Prices

The four types of salt that are produced have unique production, processing, and packaging factors that determine the selling prices. Generally, salt sold in bulk is less expensive than salt that has been packaged, pelletized, or pressed into blocks. Salt in brine is the least expensive salt sold because mining and processing costs are less. Vacuum pan salt is the most expensive because of the higher energy costs involved in processing and the purity of the product.

Price quotations are not synonymous with average values reported to the USGS. The quotations do not necessarily represent prices at which transactions actually took place or bid and asked prices. Yearend prices for salt are no longer quoted in Chemical Market Reporter; this information was last available for 1997. The average annual values, as collected by the USGS and listed in table 7, represent a national average value for each of the types of salt and the various product forms.

Foreign Trade

Under Harmonized Tariff Schedule of the United States (HTS) nomenclature, imports are aggregated under one category named "Salt (including table and denatured salt) and pure sodium chloride, whether or not in aqueous solution, seawater." The same classification also applies to exports. The HTS code for salt is 2501.00.0000. The trade tables in this report list the previous and current identification codes for salt. Although several other HTS codes pertain to various salt classifications, the United States aggregates shipments under one code because the sums of individual subclassifications fail to meet the minimum dollar requirements necessary for individual listings.

Using The Journal of Commerce's Port Import Export Reporting Service (PIERS), which provides additional information on trade data on ocean commerce (no rail or truck traffic between the United States and Canada and Mexico is included) not available from other sources, the U.S. salt industry accounted for 38% of all U.S. salt imports in 2000. The three companies that imported salt were Cargill, IMC Salt, and Morton Salt Co.. Six salt distributors represented 41% of total imports, and the domestic chloralkali industry imported 9% of total salt. Therefore, the salt industry, salt distributors, and the chloralkali industry accounted for 88% of all salt imported in 2000. The majority of U.S. salt exports in 2000 was by five domestic salt producers: Cargill, Morton Salt, U.S. Salt, United Salt, and Western Salt, Inc. According to PIERS data, these five companies exported 84% of the total.

Based on U.S. Census Bureau data, in 2000, the United States exported 642,000 t; this was a 28% decrease compared with that of 1999 (table 8). Salt was shipped to 62 countries through 32 U.S. Customs districts; the Detroit, MI, district exported the most and represented 35% of the U.S. total (table 9). In 2000, the majority of exports, or 77% of the total, was to Canada.

Based on U.S. Census Bureau statistics, the United States imported 8.96 Mt of salt from 37 countries in 2000, which was slightly more than was imported during 1999 (table 10). Table 11 lists the imports of salt by Customs districts. The quantity of imported salt was about 14 times more than that of exports. This indicates the magnitude of the United States' reliance on salt imports. The majority of imported salt was brought into the country by foreign subsidiaries of major U.S. salt producers. Generally, imported salt can be purchased and delivered to many customers at a cost lower than the comparable domestic product because production costs are lower abroad, currency exchange rates are more favorable, and ocean freight rates are less expensive than overland rail or truck rates.

World Review

Table 12 lists world salt production statistics for 111 nations based on reported and estimated information. In 2000, total world production increased slightly compared with that of 1999. The United States remained the world's leading salt-producing country, representing 21% of total world output.

Most countries possess some form of salt production capability with production levels set to meet their own domestic demand requirements and with additional quantities available for export. Many developing nations tend to develop their agricultural resources to feed their population first. Development of easily extractable mineral resources follows, and salt is one of the first commodities to be mined. Some countries, such as the United States, import a substantial amount of salt to meet total demand requirements because of economic factors.

Australia.—Intense rain and floods from Cyclone Steve in March severely affected Dampier Salt Ltd.'s solar salt production ponds at Dampier and Lake MacLeod in the northwestern part of the country. Although the storm caused production to decline by about 15%, operations were back into full production later in the year (Industrial Minerals, 2000a)

Portugal.—VA Tech Ltd. of Switzerland and Uniteca S.A., a chloralkali producer in Portugal, formed a joint venture to construct a salt plant at Carrico. The plant, with production capacity of 170,000 t/yr, was scheduled to start up in late 2001. The majority of the salt will be used as feedstock for the chlorine facility, with the remainder sold to local markets. The salt will be solution-mined from an underground deposit and crystalized in surface evaporation ponds that will be heated by a natural gas-fired cogeneration plant (Industrial Minerals, 2000e).

Russia.—A solution mining project was scheduled to begin at Koverninsky District, Nizhegorodsky Oblast, where the Belbazh salt deposit with reserves of 711 Mt was discovered in 1973. The salt brine would provide feedstock to the local chloralkali facility. Although the plan was to mine about 1 million tons per year (Mt/yr), the initial output was scheduled to be between 80,000 t/yr to 100,000 t/yr (Industrial Minerals, 2000b). In addition, a new salt facility was commissioned by the joint stock company Silvinit at Solikamsk, Perm Oblast. The plant will produce 500,000 t/yr of technical-grade salt (Industrial Minerals, 2000c).

United Kingdom.—U.S. Salt Holdings L.L.C. of the United States acquired from Stavely Industries, plc, the vacuum pan salt operation operated by British Salt Ltd. The plant at Middlewich, Cheshire, had a capacity of 825,000 t/yr. The majority of salt sales were to the chemical, food processing, and water treatment industries. The only other vacuum pan operation in England was owned by Salt Union Inc., which was purchased by IMC Global, another U.S.-owned salt company, in 1999. IMC was the world's third largest salt producer with more than 15 Mt/yr of world salt capacity (Industrial Minerals, 2000d).

Vietnam.—Two new solar salt projects were announced at Quan The and Ninh Thuan. The domestic chemical industry anticipated that its demand for salt would increase to 1 Mt/yr by 2010 from its current level of 300,000 t/yr (Bertram, 2000).

Outlook

Supplies of salt are more than adequate to meet any surge in demand for the foreseeable future. The new rock salt mines in Michigan and New York that opened recently should increase domestic rock salt production and cause rock salt imports to decline. After a couple of mild winter seasons that reduced the demand for deicing salt, it is estimated that winter weather conditions will return to traditional precipitation patterns that will require greater quantities of rock salt. U.S. production of total salt for 2001 is estimated to be 47 Mt.

NA Not available. XX Not applicable.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ As reported at salt production locations, the term "sold or used" indicates that some salt, usually salt brine, is not sold but is used for captive purposes by plant or company. Because data do not include salt imported, purchased, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ from totals shown in tables 5 and 6, which are derived from company totals.

TABLE 4
SALT SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE 1/ 2/

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Each salt type includes domestic and imported quantities. Brine is excluded because brine is not shipped out of State.

3/ Less than 1/2 unit.

4/ Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, and some shipments to upspecified destinations.

5/ Because data include salt imported, purchased, and/or sold from inventory from regional distribution centers, evaporated and rock salt distributed by State may differ from totals shown in tables 1 and 3, which are derived from plant reports at salt production locations. Data may differ from totals shown in table 5 because of changes in inventory and/or incomplete data reporting.

TABLE 7
AVERAGE VALUE OF SALT, BY PRODUCT FORM AND TYPE 1/

(Dollars per metric ton)

Product form	Vacuum and open pans	Solar	Rock	Brine
1999:				
Bulk	46.56	27.17	20.91	6.65
Compressed pellets	127.49	111.36	XX	XX
Packaged	130.88	70.15	62.60	XX
Average 2/	112.49	52.08	22.55	6.65
Pressed blocks	91.16	93.59	99.19	XX
2000:				
Bulk	50.58	21.16	19.28	5.70
Compressed pellets	130.97	112.28	XX	XX
Packaged	128.05	71.56	62.34	XX
Average 2/	113.95	50.46	20.67	5.70
Pressed blocks	101.18	93.52	91.14	XX

XX Not applicable.
1/ Net selling value, free on board plant, excluding container costs.
2/ Salt value data previously reported were an aggregate value per ton of bulk, compressed pellets, and packaged salt. For time series continuity, an average of these three types of product forms is presented that is based on the aggregate values and quantities of the product form for each type of salt shown in table 3.

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through July 10, 2001.

3/ Salt is produced in many other countries, but quantities are relatively insignificant, and reliable production data are not available. Some salt brine production data for manufacture of chlorine, caustic soda, and soda ash are not reported because of incomplete data reporting by many countries.

4/ Reported figure.

5/ Less than 1/2 unit.

6/ Year ending June 30 of that stated.

7/ From natural soda ash production.

8/ Brine salt is produced as reported by the Burmese Government in metric tons, was as follows: 1996--71,350; 1997--97,276; 1998--91,992; 1999-- 61,674; and 2000--69,245.

9/ Year beginning March 21 of that stated.

10/ Does not include production from Sardinia and Sicily, estimated to be 200,000 metric tons per year.

11/ Year ending July 15 of that stated.

12/ Data captioned "Brine salt" for the United Kingdom are the quantities of salt obtained from the evaporation of brine; that captioned "Other salt" is the salt content of brines used for purposes other than production of salt.

SAND AND GRAVEL, CONSTRUCTION

By Wallace P. Bolen

Domestic survey data and tables were prepared by Cheryl J. Crawford, statistical assistant.

Construction sand and gravel, one of the most accessible natural resources and a major basic raw material, is used mostly by the construction industry. The construction sand and gravel industry is a major contributor to and an indicator of the economic well-being of the Nation, producing a high volume of basic products with low unit value.

A total of 1.12 billion metric tons (Gt) of construction sand and gravel was produced in the United States in 2000; this was a slight increase compared with that of 1999 (table 1). After a decrease in production in 1991, sand and gravel production increased each year for the following 9 years, an indication of the continuous strong demand for construction aggregates in the United States.

In January 2001, the U.S. Geological Survey (USGS) mailed 7,892 construction sand and gravel survey forms to operations throughout the United States; an additional 372 operations that were not mailed survey forms provided information to the USGS. In 2000, 6,204 operations were active, 1,175 operations were idle, and 885 operations were either reported or assumed to be permanently shut down. A small number of the idle sand and gravel operations reported the recycling of asphalt and portland cement concrete but no sand and gravel mining. In 2000, of the 6,204 active operations surveyed, 4,272, or 68.9%, responded to the USGS survey. These operations contributed 78.2% of the 1.12 Gt produced in 2000. The 6,204 operations were run by 3,901 companies with 8,224 active sand and gravel pits (tables 9, 10).

Foreign trade of construction sand and gravel remained minor in 2000. Exports increased by about 46% to 2.41 million metric tons (Mt), but the value decreased by 13% to $24.2 million when compared with the 1999 results.

Imports increased by nearly 50% to 2.87 Mt, and their value increased by about 36% to $33.3 million. Because imports and exports were small, domestic apparent consumption of construction sand and gravel, defined as production for consumption (sold or used) plus total imports minus total exports, was essentially equal to the U.S. production of 1.12 Gt.

Legislation and Government Programs

On March 9, the U.S. Army Corps of Engineers published in the Federal Register the new nationwide permit (NWP) program that took effect June 7. The new general conditions in the NWP program affects the use of NWPs in "designated critical resource waters" and in "waters of the U.S." within 100-year floodplains. The Corps modified nine general conditions to the rule; three of these are of particular interest to the sand and gravel industry. The first condition concerns water quality and requires producers seeking NWPs to provide water quality management plans. The second concerns the management of water flows and requires activities to be designed to maintain preconstruction downstream flow conditions. Lastly, the amended general condition on mitigation requires a minimum 1:1 replacement ratio for all wetlands affected and also includes

Construction Sand and Gravel in the 20th Century

In 1900, construction sand and gravel consumption in the United States was probably about 19 million metric tons, but published statistics did not begin until 1905, when the U.S. Geological Survey reported production of about 21 million tons valued at $11.2 million. The average value was $0.53 per ton but ranged from $0.05 to $6.60 per ton. This included sand for such industrial uses as abrasive, foundry, and glassmaking sands. In 1905, production of building sand was reported to be about 9 million tons valued at $4.3 million. These sands included those used for mortar and plaster and sand used as aggregate in making concrete structures. The demand for concrete structures had increased at about the turn of the century. New York, Pennsylvania, Missouri, Indiana, and Ohio were the largest producing States in 1905, and much of the sand came from dredging the Delaware, Mississippi, Ohio, Potomac, and Tennessee Rivers and the Great Lakes. Gravel consumed in 1905 was about 4.9 million tons valued at $1.8 million and was used in concrete, roadmaking, and roofing. The average price for gravel for roofing purposes was $0.75 to $1.00 per ton.

In 2000, construction sand and gravel production was 1.12 billion tons, about 59 times the amount sold and used in 1900. Production of sand and gravel, especially from dredges in the rivers and lakes of the Eastern United States, had been mostly replaced by crushed stone operations and, to a lesser extent, sand and gravel open pits. Most sand and gravel production came from land sources. In 2000, only 12% of all operations were dredging operations, including dredges that worked in man-made lakes. The majority of sand and gravel was produced west of the Mississippi River, but Michigan and Ohio did remain among the top five States in sand and gravel production. Every State produced sand and gravel in 2000, and the largest producing State, California, produced more than seven times what the entire country produced in 1905. The average value of sand and gravel in 2000 was $4.81 per ton and ranged from $3.09 per ton for fill to about $12.35 per ton for roofing granules. The constant dollar average price of sand and gravel, which is the actual price adjusted for inflation, had not increased significantly since 1900 mostly owing to vast improvements in equipment and technologies that resulted in much greater efficiencies and productivity. More than half of the sand and gravel consumed in 2000 was used in road-related construction.

Digitized by Google

open waters in its coverage area (Aggregates Manager, 2000c).

The National Institute for Occupational Safety and Health has identified noise-induced hearing loss as 1 of the 10 leading work-related diseases and injuries in mining. Hearing loss can cause safety problems in the workplace, as well as diminish the quality of life. The loudness and the duration of noise exposure are both factors in causing hearing loss.

The Mine Safety and Health Administration's (MSHA) new rules on noise exposure went into effect September 13. The new MSHA noise rules require mine operators for the first time to enroll miners in a hearing protection program if they are exposed to an average sound level of 85 decibels or more over an 8-hour period. The program will include training, hearing tests, and providing protectors, such as ear plugs. Training will cover the dangers of noise exposure and the benefits of using protectors and how to use them. Mine operators must offer miners testing and hearing protectors, but the use of hearing protectors at that noise level will be voluntary, as will the hearing tests. (Mine Safety and Health Administration, 1999).

Production

Of the four major geographic regions, the West again led the Nation in the production of construction sand and gravel with 436 Mt, or 39% of the U.S. total (table 2). It was followed by the Midwest with 333 Mt, or 29%; the South with 244 Mt, or 22%; and the Northeast with 109 Mt, or 10%. Production increased slightly in all the major geographic regions compared with that of 1999.

Of the nine geographic divisions, the East North Central led the Nation in the production of construction sand and gravel with 225 Mt, or 20% of the U.S. total, and was followed by the Pacific and Mountain, each with 218 Mt, or 19.5% (table 2; figure 1). Production increased in five of the nine divisions compared with that of 1999—New England, 8.2%; the South Atlantic, 4.3%; the Mountain, 2.3%; the East North Central, 1.8%; and the Pacific, 1.4%. Production decreased in the East South Central, 1.9%; the West North Central, 1.8%; and the Middle Atlantic, 1.5%. Production in the West South Central was unchanged compared with that of 1999.

A review of the production for consumption by size of operation indicates that 35.8% of the construction sand and gravel produced in 2000 came from 1,939 operations reporting between 100,000 and 499,999 metric tons per year (t/yr), 25.2% came from 450 operations reporting between 500,000 and 999,999 t/yr, and 28.7% came from 208 operations reporting more than 1 million metric tons per year (Mt/yr) (table 8).

Hundreds of operations are idled, closed, or abandoned each year, and a similar number are reactivated or opened each year. The changing location of construction and highway projects each year is the major stimulus in decisions to open, idle, or close operations.

The estimated production for consumption by quarter in 2000 indicates that 30% of the construction sand and gravel in the United States was produced in the third quarter, followed by the second and the fourth quarters (table 3). Estimated production by each quarter was also available for most States (table 5).

In 2000, construction sand and gravel was produced in every State (table 4). The leading States, in descending order of tonnage, were California, Texas, Michigan, Arizona, Ohio, Colorado, Washington, Wisconsin, Minnesota, and Nevada. Their combined production represented 55% of the national total. Production increased in 24 States and decreased in 26 States compared with that of 1999. Production increased in 7 of the top 10 States; decreases occurred in Colorado, Ohio, and Washington.

Limited information about the production of construction sand and gravel in foreign countries may be found in the USGS Minerals Yearbook, Volume III, Area Reports: International. For nonreporting countries, estimates of sand and gravel and crushed stone outputs can be based on indirect indicators, such as the level of asphalt and cement consumption.

After receiving approval votes from most of their member companies, effective September 30, 2000, the National Aggregates Association and the National Stone Association merged to form the National Stone, Sand, and Gravel Association. The new association will be the sole organization representing the crushed stone and sand and gravel producing companies at the national level.

During the past 4 years (1997-2000), more than 150 acquisitions have been announced, at a rate of almost one per week. The industry consolidation is expected to continue at a very rapid pace (Aggregates Manager, 2000d).

In an industry with thousands of operating companies, there are many operating status and ownership changes. Although reviewing them all is not possible, a few noteworthy events follow.

On January 1, Aggregates Industries, Inc., announced that all its divisions would now do business under the name Aggregates Industries, dropping the individual names the divisions had been using, such as CAMAS Minnesota or Bardon Trimount (Aggregates Manager, 2000b). In 2000, Aggregates Industries was the third largest producer of sand and gravel in the United States, after ending 1999 as the fourth largest producer.

CRH plc purchased The Shelley Co. in February. The purchase included 10 sand and gravel pits and 64 fixed or portable asphalt plants (Aggregates Manager, 2000a).

Martin Marietta Materials Inc. purchased B&B Gravel Co. and three other companies in February. The purchase added 3.3 Mt/yr of capacity including sand and gravel and crushed stone (Aggregates Manager, 2000a).

In May, Florida Rock Industries, Inc., bought 12 ready-mix plants, 2 concrete block plants, and 2 sand mines from Southern Concrete Construction Co., Albany, GA. The two sand mines are located in Albany, GA, and Bainbridge, GA (Rock Products, 2000b).

Hanson plc became the largest producer of sand and gravel in the United States in 2000 with the purchase of Pioneer Concrete of America, Inc., in May, 2000. Hanson was the second largest producer in 1999 and switched positions with Vulcan Materials Co., which was the largest producer in 1999 (Rock Products, 2000a).

In March, Anglo American plc announced the purchase of Tarmac plc. In October, Anglo American sold Tarmac America, Inc., to Titan Cement Co. S.A. Titan then agreed to sell the non-Florida construction aggregate parts of Tarmac America to Vulcan Materials. This included crushed stone quarries in South Carolina and Pennsylvania and a distribution operation in Baltimore, MD. Also included were crushed stone quarries, sand and gravel operations, and marine operations in Virginia. Vulcan finalized the purchases of these operations in October and November. The remaining Tarmac America operations owned by Titan Cement will continue to do business under the name of Tarmac America (Pit and Quarry, 2000e).

Digitized by Google

In June, CSR America, Inc., agreed to purchase the aggregates and cement company FCH Holdings, Inc., and its subsidiary, Florida Crushed Stone Co. (Pit and Quarry, 2000d).

Texas Industries, Inc. (TXI), purchased Central Sand and Gravel Co. Inc. of Jena, LA, in July. Central Sand and Gravel is a primary supplier of asphalt and concrete fine and coarse aggregates in Louisiana (Pit and Quarry, 2000b). Also in July, TXI acquired Collier Sand and Gravel Co., Marble Falls, TX (Rock Products, 2000c). With these acquisitions, TXI became the 15th largest producer of sand and gravel in the United States after finishing as the 24th largest in 1999.

In September, Martin Marietta announced the purchase of the last part of Meridian Aggregates Co. that it did not own (Pit and Quarry, 2000c).

CEMEX S.A. de C.V. completed the purchase of Southdown, Inc., in November. Southdown was the seventh largest producer of sand and gravel in the United States in 1999. In 2000, CEMEX was the sixth largest producer (Pit and Quarry, 2000a).

Consumption

Construction sand and gravel reported by producers to the USGS was actually material that was "sold or used" by the companies and was defined as such. Stockpiled production is not reported until it is sold or consumed by the producer. Because no consumption surveys are conducted by the USGS for sand and gravel, the "sold or used" tonnage is assumed to represent the amount produced for domestic consumption and export. Because some of the construction sand and gravel producers did not report a breakdown by end use, their total production was reported under "Unspecified uses, reported." The estimated production of nonrespondents was reported under "Unspecified uses, estimated."

Of the 1.12 Gt of construction sand and gravel produced in 2000, 514 Mt, or 45.9% of the total, was for unspecified uses (table 6). Of the remaining 606 Mt, 43.7% was used as concrete aggregates; 22.7%, for road base and coverings and road stabilization; 13.1%, for asphaltic concrete aggregates and other bituminous mixtures; 13.3%, for construction fill; 1.7%, for plaster and gunite sands; 1.6%, for concrete products, such as blocks, bricks, pipes, etc.; and the remainder, for filtration, railroad ballast, roofing granules, snow and ice control, and other miscellaneous uses.

To provide a more accurate estimation of the consumption patterns for construction sand and gravel, the "Unspecified uses" are not included in the above percentages. In any marketing or use pattern analysis, the quantities included in "Unspecified uses" should be distributed among the reported uses by applying the above percentages.

Compared with 1999, nearly 2% more of the sand and gravel produced was reported for specific uses and this must be taken into account when analyzing changes in market consumption. Consumption increased for the following markets: filtration (about 49%), roofing granules (about 18%), concrete aggregates and miscellaneous uses (each about 11%), and fill (about 5%). Consumption decreased by about 42% for road stabilization (lime), by 12.3% for road stabilization (cement), by 4.8% for concrete products, by 2.7% for snow and ice control, and by less than 2% for plaster and gunite sands. Sand and gravel consumption for road base and coverings and railroad ballast remained at 1999 levels.

Additional information regarding production and/or consumption of construction sand and gravel by major uses in each State and the State districts may be found in the USGS Minerals Yearbook, volume II, Area Reports: Domestic.

Recycling

The aggregates industry has been involved with recycling for several decades. Recently, recycling has become more important to aggregate producers, and the number of aggregate companies that are recycling has been increasing. Recycling in this industry generally refers to the crushing, screening, and reuse of cement and asphalt concretes. Aggregate and related asphalt and ready-mix companies are often involved in construction projects where they collect and reuse the materials at the site. Some construction companies haul their materials to the recycling location where the asphalt or concrete is processed for reuse. The annual survey of construction sand and gravel producers collects information on recycling of cement and asphalt concrete performed only by sand and gravel producing companies. No information on recycling of these materials by construction or demolition companies is collected by the USGS.

Asphalt Concrete.—A total of 4.74 Mt of asphalt concrete valued at $21.6 million was recycled by 198 sand and gravel companies in 39 States; this volume represented a 26% decrease compared with that of 1999 (tables 14, 15). Leading States, in descending order of tonnage recycled, were California, Minnesota, and Wisconsin. Leading companies, in order of volume produced, were Granite Construction Co.; Red Flint Group, LLC; Provident Engineering and Development Co.; Memphis Stone and Gravel Co.; and Central Specialties, Inc.

Cement Concrete.—A total of 7.21 Mt of cement concrete valued at $32.6 million was recycled by 182 companies in 35 States; this volume represented a 7.9% increase compared with that of 1999 (tables 14, 16). Leading States, in descending order of tonnage recycled, were California, Minnesota, Michigan, and Wisconsin. Leading companies, in order of volume produced, were Premier Aggregates, Inc.; Vulcan Materials; Custom Crushing and Recycling, Inc.; Red Flint Group; and Provident Engineering and Development.

Transportation

Information regarding the method of transportation of construction sand and gravel from the pit or processing plant to the first point of sale or use is available for each geographic region, as well as for the total United States, and is listed in table 11. Reports regarding the method of transportation were provided by the producers for 547 Mt, or 49% of the total U.S. production, of construction sand and gravel. Of this total, 78.8% was transported by truck; 3.1%, by waterway; and 1.6%, by rail. A significant amount of construction sand and gravel produced (about 15%) was not transported but was used at the production site. Because most producers either did not keep records or did not report shipping distances or cost per metric ton per mile, no transportation cost data were available.

Prices

Prices in this chapter are "free on board" (f.o.b.) plant, usually at the first point of sale or captive use. This value does not include transportation from the plant or yard to the

Digitized by Google

consumer. It does, however, include all costs of mining, processing, in-plant transportation, overhead costs, and profit.

The 2000 average unit price increased by about 1.7% to $4.81 per metric ton, compared with that of 1999 (table 6). By use, the unit prices varied from a high of $12.35 per ton for roofing granules to a low of $3.09 per ton for fill. The largest increases were recorded for roofing granules (80.6%), railroad ballast (18.7%), and road stabilization (cement) (16.2%). Only two markets recorded declines: concrete products (4.2%) and other uses (1.8%).

Foreign Trade

The widespread distribution of domestic sand and gravel deposits and the high cost of transportation limits foreign trade to mostly local transactions across international boundaries. U.S. imports and exports were small, representing less than 1% of the domestic consumption.

Exports of construction sand increased by about 69% to 2.14 Mt compared with that of 1999 and the value increased by nearly 2% to $21.2 million (table 12). Mexico was the major destination, receiving about 75% of the total, followed by Canada with nearly 16%. Exports of construction gravel decreased by almost 29% to 270,000 metric tons, and the value decreased by about 57% to $3.03 million. Canada was the major destination, receiving about 84% of the total.

Imports increased by about 49% to 2.87 Mt, and the value increased by about 36% to $33.3 million (table 13). Canada was the major source of imported construction sand and gravel with 56% of the total, followed by Mexico with about 25%.

Outlook

The demand for construction sand and gravel in 2001 is expected to be about equal to that of 2000 in response to a slowing national economy. There are some indications from the quarterly survey that a slowing economy has stalled growth in aggregate demand through the first half of 2001 but some regions of the United States should see increased sales so that overall demand will likely remain close to 2000 levels.

Construction sand and gravel f.o.b. prices are expected to increase only marginally. The delivered prices of construction sand and gravel, however, are expected to increase especially in and near metropolitan areas mainly because more aggregates are transported from distant sources.

For 2001, the industry is expected to continue to consolidate. Resistance to mining, especially at the local level, will push production to more rural areas and increase transportation cost. The cost to acquire existing companies will escalate because of the difficulty of starting greenfield operations. It is estimated that it now takes from 5 to 8 years to put a new resource (greenfield) into production. This includes the time it takes to prove the reserve base, receive zoning and permit approvals, and to deliver and install the necessary equipment. Also, throughout the process, the possibility exists that the project may have to be abandoned because of local opposition and permit or zoning denial; therefore, many companies prefer to buy already permitted active operations rather than face the cost and uncertainties involved with a greenfield operation.

TABLE 1
SALIENT U.S. CONSTRUCTION SAND AND GRAVEL STATISTICS 1/

(Thousand metric tons and thousand dollars)

	1996	1997	1998	1999	2000
Sold or used by producers:					
Quantity 2/	914,000 3/	952,000	1,070,000	1,110,000	1,120,000
Value 2/	4,000,000 3/	4,260,000	4,910,000	5,250,000	5,390,000
Exports, value	23,300	22,300	37,800	27,900	24,200
Imports, value	15,800	18,100	15,000	24,400	33,300

1/ Data are rounded to no more than three significant digits.
2/ Puerto Rico excluded from all sand and gravel statistics.
3/ Excludes Hawaii.

TABLE 2
CONSTRUCTION SAND AND GRAVEL SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY GEOGRAPHIC DIVISION 1/

	1999				2000			
Region/division	Quantity (thousand metric tons)	Percentage of total	Value (thousands)	Percentage of total	Quantity (thousand metric tons)	Percentage of total	Value (thousands)	Percentage of total
Northeast:								
New England	41,500	3.7	$213,000	4.1	44,900	4.0	$235,000	4.3
Middle Atlantic	64,900	5.9	359,000	6.8	63,900	5.7	349,000	6.5
Midwest:								
East North Central	221,000	20.0	903,000	17.2	225,000	20.0	927,000	17.2
West North Central	110,000	9.9	403,000	7.7	108,000	9.6	396,000	7.3
South:								
South Atlantic	79,900	7.2	375,000	7.2	83,300	7.4	406,000	7.5
East South Central	46,800	4.2	213,000	4.1	45,900	4.1	208,000	3.8
West South Central	115,000	10.4	549,000	10.5	115,000	10.2	569,000	10.5
West:								
Mountain	213,000	19.2	949,000	18.1	218,000	19.5	988,000	18.3
Pacific	215,000	19.4	1,280,000	24.5	218,000	19.4	1,320,000	24.4
Total	1,110,000	100	5,250,000	100	1,120,000	100	5,390,000	100

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

TABLE 3
SAND AND GRAVEL SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 2000, BY QUARTER AND DIVISION 1/

	Quantity 1st quarter		Quantity 2d quarter		Quantity 3d quarter		Quantity 4th quarter		Total 2/	
Region/division	(thousand metric tons)	Percentage change 3/	(thousand metric tons)	Percentage change 3/	(thousand metric tons)	Percentage change 3/	(thousand metric tons)	Percentage change 3/	Quantity (thousand metric tons)	Value (thousands)
Northeast:										
New England	5,400	4.5	12,000	1.3	15,200	9.4	10,300	(1.8)	43,000	$228,000
Middle Atlantic	8,800	6.8	19,600	3.0	22,900	0.4	14,800	(1.1)	66,000	375,000
Midwest:										
East North Central	28,800	7.1	63,600	(0.1)	70,300	(4.2)	53,600	(6.9)	216,000	907,000
West North Central	11,900	16.9	36,700	13.7	40,600	(0.6)	21,700	(19.3)	111,000	427,000
South:										
South Atlantic	19,300	3.3	22,400	1.5	21,800	5.3	20,100	9.1	83,600	412,000

Total	XX	XX	XX	XX	XX	XX	XX	XX	1,160,000	5,610,000

XX Not applicable. -- Zero.

1/ As published in the Crushed Stone and Sand and Gravel in the Fourth Quarter of 2000 Mineral Industry Surveys.

2/ Data may not add to totals shown because of independent rounding and differences between projected totals by States and regions.

3/ All percentage changes are calculated by using unrounded totals; percentage changes are based on the previous year's corresponding quarter.

4/ State not included in quarterly survey.

5/ Owing to a low number of reporting companies, no production estimates by quarters were generated.

TABLE 6
CONSTRUCTION SAND AND GRAVEL SOLD OR USED IN THE UNITED STATES IN 2000, BY MAJOR USE 1/

Use	Quantity (thousand metric tons)	Value (thousands)	Unit value
Concrete aggregates (including concrete sand)	265,000	$1,450,000	$5.48
Plaster and gunite sands	10,200	62,800	6.15
Concrete products (blocks, bricks, pipe, decorative, etc.)	9,810	62,000	6.32
Asphaltic concrete aggregates and other bituminous mixtures	79,500	452,000	5.69
Road base and coverings	132,000	568,000	4.31
Road stabilization (cement)	3,340	17,000	5.10
Road stabilization (lime)	2,520	9,880	3.93
Fill	80,800	250,000	3.09
Snow and ice control	5,360	22,000	4.11
Railroad ballast	1,070	7,160	6.67
Roofing granules	471	5,820	12.35
Filtration	1,720	10,500	6.10

SELENIUM AND TELLURIUM

By Robert D. Brown, Jr.

Domestic survey data and tables were prepared by Lisa D. Miller, statistical assistant, and the world production tables were prepared by Ronald L. Hatch, lead international data coordinator.

Selenium and tellurium are byproduct metals usually associated with copper production. Primary selenium was produced domestically as a byproduct of copper refining in 2000; secondary (recycled) selenium was not produced. Five electrolytic copper refineries generated selenium-containing anode slimes. One of the refineries recovered commercial-grade selenium; one recovered a semirefined filter cake, which was shipped to Asia for further refining; and three exported anode slimes for refining. Domestic production increased in 2000.

Selenium use as a photoreceptor for plain-paper copiers has been decreasing in recent years and declined again in 2000 in favor of cheaper organic compounds. The distribution among other end-use sectors remained nearly the same, except that metallurgical applications increased. Estimates of end-use demand in 2000 are as follows: glass, 25%; metallurgical applications, 24%; miscellaneous chemical uses, 14%; photoreceptors, 10%; pigments, 8%; and other uses, including agricultural feed additives, 19%.

About 250 metric tons (t) of secondary selenium is produced every year worldwide. World refinery production of primary selenium (excluding U.S. production withheld to protect proprietary data) increased 4%, to 1,460 t; the largest producers, excluding the United States, in decreasing order of output, were Japan, Canada, Belgium, and Germany. These countries accounted for 86% of world refined selenium production in 2000.

World producers of refined tellurium were Canada, Japan, Peru, and the United States. Domestically, tellurium was recovered by one company from anode slimes generated in the electrolytic refining of copper and from soda slag skimmings generated in lead refining. Secondary tellurium was not produced domestically, but some scrap was exported for recycling. Production data reported to the U.S. Geological Survey are treated as company proprietary information. Domestic consumption is believed to have increased in 2000. About 55% of the tellurium was used as free-machining additives to steel. Other uses included catalysts, chemical uses, nonferrous alloys, photoreceptors, thermoelectric devices, and digital video discs.

Domestic Data Coverage

Domestic data are collected through a voluntary survey of U.S. selenium and tellurium producers. The production survey was sent to the two known domestic producers of selenium and the sole domestic producer of tellurium. All the companies responded to the survey. In order to protect proprietary interests of the companies, however, it is necessary to withhold the survey data from publication.

Production

Selenium.—Selenium was recovered from anode slimes generated in the electrolytic production of copper. Because selenium is a byproduct of copper production, its output cannot be easily adjusted to meet market conditions. Therefore, the selenium market is subject to supply and price fluctuations. Domestic production was higher than that in 1999. Only one domestic copper refinery recovered selenium—ASARCO Inc., Amarillo, TX. One producer exported semirefined selenium (90% selenium content) for toll-refining in Asia.

Three other companies generated selenium-containing slimes, but did not produce selenium. Selenium-containing slimes from these refineries were exported for processing.

Most domestic selenium was produced as commercial-grade metal, averaging a minimum of 99.5% selenium and available in various forms, including shot, lump, and powder or pigment-grade powder having a minimum 99.8% selenium content.

Hydromet Environmental Recovery Ltd. will accept waste material for the recovery of tin and selenium at its new plant scheduled to open during 2001 in Newman, IL. The plant expects to process selenium materials from both the copper refining and photocopy industries (American Metal Market, 2000b).

Tellurium.—Commercial-grade tellurium and tellurium dioxide were produced by Asarco, Amarillo, TX, mainly from copper anode slime but also from lead refinery skimmings. Asarco also produced high-purity tellurium (99.999% purity) and selenium (99.999% purity) and other high-purity metals and compounds at its plant in Denver, CO. Domestic tellurium production decreased in 2000, compared with that for 1999.

Consumption

Selenium.—Selenium demand by end use can be divided broadly into the following categories: glass manufacturing, electronics (including photoreceptor uses), agricultural uses, metallurgical applications, chemicals, and pigments.

In glass manufacturing, selenium is used principally as a decolorant in container glass and other soda-lime silica glasses. Under weak oxidizing conditions, the addition of selenium adds a pink color to the glass that combines with the green color imparted by ferrous ions to create a neutral grey color that has low perceptibility to the human eye. Selenium is also used to reduce solar heat transmission in architectural plate glass and to add red color to glass, such as that used in traffic lights. Glass manufacturing accounted for about 25% of the selenium market in 2000.

Metallurgical uses comprised an estimated 24% of the selenium market. It is estimated that more than one-half of the

Digitized by Google

metallurgical selenium is used as an additive to steel, copper, and lead alloys to improve machinability and casting and forming properties. Several domestic producers of rolled steel bar produce selenium-bearing free-machining rod. Selenium-containing free-cutting steels, however, are generally cost competitive only when used with high-speed automatic machine tools.

Selenium (with bismuth) can replace lead in plumbing applications because they provide the same free-machining properties as lead without its negative environmental effects (King and Li, 1997). The Safe Drinking Water Act Amendments of 1996 (Public Law 104-182) requires that all pipes, fixtures, solders, and fluxes used for the installation or repair of facilities providing water for human consumption contain no lead after August 1998. Boosted by the goal set by Public Law 104-182, selenium use in plumbing continued to increase in 2000.

The Copper Development Association has changed the name of its alloys introduced in 1995 as SeBiLOY (containing selenium and bismuth) to Envirobrass to highlight the significant environmental and health benefits to manufacturers and consumers. Envirobrass I and II contain a mixture of bismuth and selenium substituted for lead in red brasses used for water meters, valves, and plumbing fixtures. A new alloy, Envirobrass III is a lead-free yellow brass for permanent mold casting (Payne, 2000).

A smaller amount of metallurgical selenium is used as an additive to low-antimony lead alloys forming the support grids of lead-acid storage batteries. The addition of 0.02% selenium by weight as a grain refiner improves the casting and mechanical properties of the alloy. Hybrid batteries, which employ low-antimony lead positive plates and lead-calcium negative plates, have been gaining in usage, thus increasing the demand for selenium.

Other uses, mainly agricultural, compose about 19% of the selenium market. Dietary supplements for livestock are the largest agricultural use. Selenium also may be added to fertilizer used in growing animal feed, a practice that is more prevalent outside the United States.

Electronics, which is a decreasing end-use market, accounted for 10% of selenium use. High-purity selenium compounds were used principally as photoreceptors on the drums of plain-paper copiers. Photoreceptors had been the largest single application for selenium during the 1970s and 1980s. Selenium compounds, however, are being replaced by organic photoreceptor compounds (OPC), which reportedly offer better performance and lower cost at printing speeds under 80 pages per minute and comparable cost and performance at faster printing speeds. OPCs also are free of the environmental concerns associated with the disposal of selenium compounds. Other electronic uses of selenium included rectifier and photoelectric applications.

Chemical uses of selenium, including industrial and pharmaceutical applications, accounted for about 14% of usage. Selenium is gaining greater recognition as a nutrient essential for human health; small but increasing quantities of selenium are used as human dietary supplements. As ongoing research verifies the apparent cancer-preventative properties of selenium, this application is increasing, but the low dosage requirement precludes it from becoming significant in terms of quantity consumed. The principal pharmaceutical use of selenium is in antidandruff shampoos. Miscellaneous industrial chemical uses include lubricants, rubber compounds, and catalysts.

In pigment applications, selenium is used to produce color changes in cadmium-sulfide-based pigments. Yellow cadmium pigment becomes more red as the selenium-to-sulfur ratio increases. Sulfoselenide red pigments have good heat stability and are used in ceramics and plastics as well as in paints, inks, and enamels. Because of the relatively high cost and the toxicity of cadmium-based pigments, their use is generally restricted to special applications requiring any combination of long life, brilliance, high thermal stability, or chemical resistance. Pigments accounted for about 8% of the selenium market.

Tellurium.—World demand for tellurium increased in 2000. The largest use for tellurium was as an additive to free-machining steel, about one-half of the market. Chemicals and catalyst usage made up about 25% of the market. Additives to nonferrous alloys accounted for slightly more than 10% of total use, and photoreceptor and thermoelectric applications accounted for slightly less than 10%. Other uses were about 5%.

As an alloying element in the production of free-machining low-carbon steels, additions of up to 0.1% tellurium, usually in conjunction with lead, greatly improve machinability. Similarly, the addition of tellurium to copper and other nonferrous alloys improves their machinability, strength, and corrosion resistance. Tellurium catalysts are used chiefly for the oxidation of organic compounds but are also used in hydrogenation, halogenation, and chlorination reactions. Tellurium dioxide is used as a curing and accelerating agent in rubber compounds.

Electronic semiconductor applications for high-purity tellurium include its use in thermoelectric and photoelectric devices and with selenium as a photoreceptor in plain-paper copiers. Mercury-cadmium-telluride is used as a sensing material for thermal imaging devices. Thermoelectric cooling devices, based on bismuth telluride semiconducting materials, are finding wider application in electronics and for some consumer products. These devices consist of a series of couples composed of different semiconducting materials which, when connected to a direct current, cause one side of the thermoelement to cool while the other side generates heat. The warm side is connected to a heat sink to dissipate the heat. Although thermoelectric coolers are still used more in military and electronic applications, such as the cooling of infrared detectors, integrated circuits, medical instrumentation, and laser diodes, their use in consumer products, such as portable food-and-beverage coolers, continued to increase. New applications include a germanium-antimony-tellurium compound used for optical storage on digital video discs (Metal Bulletin Monthly, 2000).

Prices

The domestic producer price for selenium averaged $3.84 per pound in 2000. Beginning the year at $2.78 per pound, the domestic producer price rose steadily to $4.30 per pound in

Digitized by Google

early March, held firm for a month, and then retreated to $4.25 during April and May. In June, the price fell to $3.95 per pound and held steady for 4 months. During the last quarter of the year the price fell to $3.85 per pound in October, then to $3.25 per pound in mid-November where it remained for the rest of the year. The producer price for tellurium fell to $14 per pound by yearend, averaging about $14.50 for the year.

Trade

International trade is important in U.S. selenium and tellurium markets. In 2000, imports of selenium increased significantly (46%), while exports decreased markedly (65%). The United States was a net importer of selenium by 390 t including the selenium content of selenium dioxide compared with only 93 t in 1999. Canada, the Philippines, and the Republic of Korea (in order of decreasing quantity) were the leading foreign suppliers of selenium. They accounted for 86% of the imports of selenium metal to the United States in 2000. Imports of tellurium increased by 38% during the year. The leading suppliers were the United Kingdom, the Philippines, Belgium, and Canada. Data for tellurium exports were not available.

World Review

Overall, the world selenium market remained fairly well balanced, with a tendency toward excess supply replaced by steady production matched by strong increased demand from China (Metal Bulletin, 2000c). World production and consumption data for selenium and tellurium are limited. It is estimated that production of both selenium and tellurium, along with that of copper itself, increased in 2000 despite various interruptions, cutbacks, and closures in the copper industry. World production of the byproducts has been fairly steady over the past few years. Supply and demand have been in fairly close balance for several years. Better productivity has increased the possibility of oversupply, placing some downward pressure on prices. But cuts in copper production and the increased use of solvent extraction-electrowinning could shift the trend toward lower selenium and tellurium availability (Mining Journal, 2000b). Also, increased consumption of selenium in China, a net importer already, put upward pressure on prices for 2000 (Mining Journal, 2000a).

In the Philippines, the Philippine Associated Smelting and Refining Corp. announced plans for a substantial increase in copper production which will lead almost certainly to increases in selenium output (Mining Journal, 2001).

In Japan, total selenium demand is increasing in spite of lower consumption for photocopiers. Consumption is growing for glass, paint, pharmaceuticals, and shampoos. As the world's largest selenium supplier, Japan focuses on selenium export markets. Even so, as consumption increases, Japanese selenium exports have been dropping slightly every year since 1997. Considering the various worldwide production cutbacks, there is some concern over supply (Roskill's Letter from Japan, 2000).

In Belgium, Savi Alloys, N.V., sold its selenium production operations and will concentrate on bismuth and tellurium (Metal Bulletin, 2000b).

Current Research and Technology

Until recently, selenium has been one of the least celebrated human nutrients because selenium deficiencies are rare (in the United States) and its toxicity is a risk. The toxicity risk overshadowed the use of selenium as a human supplement, although the necessity of providing selenium in the diet of farm animals has been well established for years. In the past few years, research has revealed that human selenium supplementation may provide significant reductions in the occurrence rate of lung, prostate, and colorectal cancers. Medical tests have shown that, compared with a placebo group, cancer incidence among the patients receiving selenium was 46% lower for lung cancer, 48% lower for colorectal cancer, and 63% lower for prostate cancer (Clark and others, 1996).

Further testing and research is continuing and was reported on extensively in medical and popular health journals during 2000. The U.S. National Cancer Institute is funding the 12-year Selenium and Vitamin E Cancer Prevention Trial (SELECT) in the United States. The trial will seek to enroll more than 32,000 men to test the effect of selenium and vitamin E on the incidence rate of prostate cancer (Tracey, 2001). The Prevention of Cancer by Intervention with Selenium (PRECISE) trial in Europe will involve 33,000 men in three countries, Denmark, Sweden, and the United Kingdom. The SELECT and PRECISE trials are attempts to replicate the encouraging results of the 1996 trial on a larger scale. When too much selenium is taken by humans, it becomes toxic. The maximum safe level has been determined by several expert panels to be 400 to 450 micrograms per day form all sources, including diet and supplementation (Rayman, 2000).

In China, research has shown that variations in human selenium levels affect the incidence rate of esophageal and gastric cardia cancers. There was strong statistical evidence that increased selenium levels lowered the incidence of these cancers. Selenium levels were measured in about 1,000 patients with these cancers and in 1,000 subjects who did not have these cancers (Mark, 2000).

A new solar cell, based on a copper/indium/selenium compound has been developed in Germany. Cis-Solartechnik, GmbH, partly owned by Norddeutsche Affinerie AG, will continue development work on the new product, which is made mostly by deposition through galvanic processes onto a flexible copper strip. The new cell, with greater than 10% efficiency, is light in weight and extremely tough (American Metal Market, 2000a).

Evidence mounts that tellurium is not as toxic as generally thought. An 18 month old boy ingested tellurium dioxide in a hydrogen chloride solution. Although his serum tellurium levels were six times normal, there was no clinical evidence of tellurium toxicity (Higgins and others, 1999).

Outlook

Demand for selenium in photoreceptors, except where they are required for existing photocopiers, is likely to continue declining as the cost of substituting organic compounds decreases. A number of new uses have been developed, and they are beginning to affect the overall demand for selenium.

Digitized by Google

Use as an additive to plumbing brasses, as part of the effort to use lead-free alloys, affords the greatest possibility for significant increases in demand.

As a byproduct of copper production, the outlook for selenium supply and price could be significantly affected by events in the copper industry (Metal Bulletin, 2001). When a copper plant closes or uses processes that do not generate anode slimes, the ultimate amount of selenium that can be produced is decreased (Platt's Metals Week, 2000). Thus, if current demand levels remain steady or increase, prices could continue to rise well above the lows that occurred in the past decade (Metal Bulletin, 2000a).

Chinese demand is still increasing, but there is no significant domestic production; consequently, China is dependent on imports, mostly from Japan. This growing import reliance suggests that Chinese producers may not be able to introduce low-cost supplies in the world selenium market when prices increase (Mining Journal, 2000b).

Further use of selenium in cancer prevention may eventually lead to profound public health benefits. However, this important application for selenium will not induce a large increase in demand for the metal because only small dosages of it would be necessary for effective therapy.

Tellurium supply and demand have remained in fairly close balance for a decade. Large increases are not foreseen in either consumption or production for the immediate future. The demand for high-purity tellurium for solar cells and electronic devices could increase and this would have a major impact on tellurium consumption.

e/ Estimated. p/ Preliminary. r/ Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Insofar as possible, data relate to refinery output only; thus, countries that produced selenium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but did not recover refined selenium from these materials indigenously were excluded to avoid double counting. Table includes data available through June 9, 2001.

3/ In addition to the countries listed, Australia produced refined selenium, but output was not reported; available information is inadequate to formulate reliable estimate of output levels. Australia is known to produce selenium in intermediate metallurgical products and has facilities to produce elemental selenium. In addition to having facilities for processing imported anode slimes for the recovery of selenium and precious metals, the United Kingdom has facilities for processing selenium scrap.

4/ Excludes selenium intermediates exported for refining.

5/ Data are for Indian fiscal year beginning April 1 of year stated.

6/ Reported figure.

7/ Includes production of semirefined selenium exported for further refining.

8/ Data are for year beginning April 1 of year stated. Gross weight, purity unknown.

SILICA

By Thomas P. Dolley and Wallace P. Bolen

Domestic survey data and tables were prepared by Nicholas A. Muniz, Raymond I. Eldridge III, and Christine K. Pisut, statistical assistants, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Four silica categories are covered in this report—industrial sand and gravel, quartz crystals, special silica stone products, and tripoli. Most of the stone covered in the special silica stone products section is novaculite. The section on tripoli includes tripoli and other fine-grained, porous silica materials that have similar properties and end uses, such as rottenstone. Certain silica and silicate materials, such as pumice and diatomite, are covered in other chapters of the U.S. Geological Survey (USGS) Minerals Yearbook.

Industrial Sand and Gravel

Total industrial sand and gravel production decreased by 1.7% to 28.4 million metric tons (Mt) in 2000 compared with that of 1999 (table 1). Compared with those of 1999, industrial sand production decreased by less than 1%, and gravel production decreased by about 14%. Exports decreased by less than 1% compared with those of 1999, and imports increased by 17% to 247,000 metric tons (t).

Industrial sand and gravel, often called "silica," "silica sand," and "quartz sand," includes sands and gravels with high silicon dioxide (SiO_2) content. These sands are used in glassmaking; for foundry, abrasive, and hydraulic fracturing (frac) applications; and for many other industrial uses. The specifications for each use vary, but silica resources for most uses are abundant. In almost all cases, silica mining uses open pit or dredging mining methods with standard mining equipment. Except for temporarily disturbing the immediate area while mining operations are active, sand and gravel mining usually has limited environmental impact.

The production decrease was minimal after several years of increasing demand for sand for many uses, including ceramics, chemicals, fillers (ground and whole grain), filtration, flat and specialty glass, hydraulic fracturing, recreational, and roofing granules. The demand for silica gravel, which was used for filtration and nonmetallurgical flux, experienced a significant decrease. Decreases in the production and sale of silica can be attributed in part to the decline of growth in the economy in 2000.

Legislation and Government Programs.—The regulation of respirable silica continued to concern miners and consumers of many minerals that contain crystalline silica, especially the industrial sand and gravel industry. One of the most important issues to have had an impact on the industrial minerals industry in recent times has been the question of crystalline silica and its effect on human health. Central to the ongoing and often heated debate has been the understanding and implementation of the measurements, the regulations, and the actions taken with regard to exposure to crystalline silica and, most significantly, the appreciation of its impact on the future of many industries (Industrial Minerals, 1998a).

Production.—Domestic production data for industrial sand and gravel were derived by the USGS from a voluntary survey of U.S. producers. The USGS canvassed 69 producers with 154 operations known to produce industrial sand and gravel. Of the 154 surveyed operations, 130 (84%) were active, and 24 were idle. The USGS received responses from 112 operations, and their combined production represented about 78% of the U.S. total. Production for the 31 nonrespondents was estimated, usually based on previously reported information supplemented

Silica in the 20th Century

In 1902, 10 States reported production of "glass sand" for glassmaking, engine or traction sand, furnace sand, building sand, and miscellaneous uses. A total of 1.7 million metric tons valued at $1.42 million was reported. The commercial production of glass sand was reported from the States of Illinois, Indiana, Maryland, Massachusetts, Missouri, New Jersey, New York, Ohio, Pennsylvania, and West Virginia. Besides silica sand, various silica stones were used as abrasive material. The value of grindstones produced in 1900 was $710,000, breaking the old record set in 1882. The production of infusorial earth and tripoli was 3,280 tons valued at $24,000. The production of millstones in 1900 was the largest since 1889, but the industry was still of insignificant importance compared with where it had been 20 years earlier. The substitution of the roller process for buhrstone in flour mills had practically eliminated the use of buhrstones for that purpose. The value of the oilstones and whetstones made in the United States in 1900 was $174,000, a decrease from 1899, when the largest production in the history of the industry had occurred.

In 2000, the United States was the largest producer and consumer of industrial silica, which included industrial sand and gravel, tripoli, special silica stone, and electronic- and optical-grade quartz crystal. U.S. production of industrial sand and gravel amounted to 28.4 million tons. U.S. exports of industrial sand and gravel totaled 1.66 million tons. Silica was arguably one of the most versatile industrial minerals in the 20th century. The most important uses of industrial silica were as glass sand, ceramics, and foundry sand. Other uses included metallurgical applications, abrasives, fillers, filtration, and hydraulic fracturing of rock formations to improve recovery in oil wells. Additionally, electronic-grade quartz crystal was used to accurately control frequency, in timers, and in filters in aerospace hardware, communications equipment, computers, consumer goods (e.g., clocks, games, television receivers, and toys), and navigation instruments.

Digitized by Google

with man-hour reports from the U.S. Department of Labor's Mine Safety and Health Administration and information from State agencies.

The Midwest region (east-north-central and west-north-central divisions) continued to lead the Nation with about 40% of the 28.4 Mt of industrial sand and gravel produced in the United States, followed by the South (south Atlantic, east-south-central, and west-south-central divisions) with about 39% and the West (Pacific and mountain divisions) with 12% (table 2, figure 1).

The eight leading producing States, in descending order, were Illinois, Michigan, California, Wisconsin, Texas, New Jersey, North Carolina, and Oklahoma (table 3). Their combined production represented about 60% of the national total. Production remained relatively stable in all these States, except New Jersey and Texas, which had increased production from 1999 to 2000. Of the 36 States producing in 2000, 18 had increased production, 17 had decreased production, and 1 stayed about even compared with 1999. Mississippi, Texas, and New Jersey reported the largest increases, and Minnesota, Idaho, New York, and Arizona reported the largest decreases.

About 82% of the total industrial sand and gravel was produced by 51 operations, each with production of more than 200,000 tons per year (t/yr) (tables 4, 5). The 10 leading producers of industrial sand and gravel, in descending order, were Unimin Corp., U.S. Silica Co., Fairmount Minerals Ltd., Oglebay Norton Industrial Sands Co., Badger Mining Corp., Nugent Sand Co. Inc., Construction Aggregates Corp., Simplot Industries Inc., Little Six Corp., and Manley Brothers, Inc. Their combined production from 59 operations represented 76% of the U.S. total.

Unimin Corp. purchased the operation of Owen Illinois, Inc. of Amador County, CA, in July. The operation, near Ione, CA, processes silica from a kaolin/silica deposit, and most of the silica has traditionally been used for container glass manufacturing, although the amount of silica sold for other uses has been increasing. Unimin also operates a silica mine and plant near Byron, in Contra Costa County, CA.

In July, CSR America, Inc. purchased Florida Crushed Stone Co., which included Montgomery Sand Co. in Montgomery County, GA. The Mount Vernon, GA, operation produced both construction and industrial sand and gravel.

Oglebay Norton Specialty Minerals, Inc. purchased the Franklin Industrial Minerals operation in Cleveland County, NC. The plant is near Kings Mountain, NC, and processes silica from a weathered pegmatite that contains feldspar, kaolin, mica, and silica. Much of the sand is a feldspathic sand that is suitable for ceramics, glassmaking, and other uses in which alumina content is desirable.

Consumption.—Sand and gravel production reported by producers to the USGS was material sold to their customers or used by the companies. Stockpiled material is not reported until consumed or sold. Of the 28.4 Mt of industrial sand and gravel sold or used, about 38% was consumed as glassmaking sand and 22% as foundry sand (table 6). Other important uses were abrasive sand (4.6%) and frac sand (4.9%). Building products, a broad category that includes nonskid flooring, paints, putty, and stucco, consumed about 7.4% of industrial sand and gravel production.

Exploitable resources of industrial sand and gravel occur throughout the United States, and successful mining companies are responding to market locations, which have traditionally been in the Eastern United States. Occasionally, consuming industries are specifically located near a silica resource. Because of the abundance of silica deposits, locating near a silica resource has not always been a priority, although it certainly has been a consideration. The auto industry was originally located in the Midwest near clay, coal, iron, and silica resources. Therefore, foundry sands have been greatly exploited in Illinois, Indiana, Michigan, Ohio, and other Midwestern States. In 2000, over 80% of foundry sand was produced in the Midwestern region.

Conversely, the glass industry had to locate plants where it could minimize the shipping distance of finished glass products (container, flat, etc.). Hence, glass plants were more evenly distributed. In 2000, 43% of glass sand was produced in the South; 30%, in the Midwest; 15%, in the West; and 12%, in the Northeast. To varying degrees, all silica production and sales are similarly influenced by the location of the consuming industries.

Some improvements in data collection affected the distribution by market segment for glass sand. Because of this improvement, some sand consumption formerly attributed to container and fiberglass production was placed in the flat and specialty segments. Therefore, although the increasing or decreasing trends in each market accurately reflects the growth in the various glass segments, the actual increase or decrease is likely not as large as the statistics portray.

The share of silica sold for all types of glassmaking as a percentage of all silica sold was a little more than 38%. This percentage has remained stable compared with that of 1999. In 2000, sales to container glass manufacturers decreased by 8% compared with those of 1999. The amount of sand consumed for fiberglass production dropped by 4.8% compared with 1999.

In 2000, sales of sand for flat glass production increased by nearly 2.7% compared with those of 1999. In the South region, consumption for flat glass increased by 1.8%, and in the Midwest region, there was a 1.6% decrease.

Specialty glass consists of many segments, but the largest portion of it is laboratory and lighting glass (light bulbs, fluorescent, etc.). Specialty laboratory glass also makes up part of the apparatus used in many segments of the electronics industry, including in the production of optical fiber and semiconductors.

The U.S. fiberglass industry consists of four major insulation manufacturers and six major textile producers. Continuous glass fiber specifications are very strict. Batch grain-size control is very important, so ground silica (ultrafine powder) is used. Iron, potassium, and sodium oxide content is tightly controlled. The raw mix is fused at 1,600° C and then passed through platinum bushings at 1,300° C. Various mineral wools are fabricated using basalt and diabase (rock wool), glass (glass wool), or blast furnace slag (slag wool) (Industrial Minerals, 1998c).

Silica is used in ceramics in whole grain and ground forms. Generally, whole-grain silica is used about 22% to 32% in the ceramic body of sanitaryware (sinks, toilets, urinals, etc.). Ground silica is used to decrease viscosity and the expansion coefficient in ceramic glazes and other ceramic applications. A typical glaze composition consists of about 25% quartz or silica. In 2000, about 278,000 t of ground silica was used in ceramic production.

Digitized by Google

Advanced ceramics, such as silicon nitride and silicon carbide, represent a growing market for silica and silica-based chemicals. Silicon carbide is manufactured by cooking silica sand or crushed quartz and oil coke at 2,400° C in an electric furnace for several days; sawdust or rice husks are added to increase porosity. Silicon carbide's thermal conductivity and expansion coefficient make it especially useful in the refractory industry (Industrial Minerals, 1998c).

The production of industrial-grade silicon carbide was on the order of 800,000 t/yr. Applications for silicon carbide include wear parts, such as seal rings, slide bearings, shafts, and dynamic pressure, or composite bearings used in a variety of pumps. The global market for silicon nitride, which is based on powder use, is estimated to be 300,000 t/yr. Primary markets for hybrid bearings, which are based on these materials, are machine tool spindles, aerospace components, and instruments such as dental drills, vacuum systems, and gyroscopes. Other markets for silicon nitride include engine components and cutting tools (Ceramic Industry, 1998).

Silica is also used in plastics as an extender, filler, and reinforcer. Whole-grain and ground silica are used in filler-type applications. Ground silica is used to thicken liquid systems, to avoid plateout in polyvinyl chloride, as a thixotropic and flatting agent, and in many other filler applications. Other silica (whole grain and ground) uses include nonskid flooring, paints, putty, stucco, and other building product applications. Silica is also used in paint because it offers acid, scrubbing, and wear resistance. As segregated for this survey, consumption in 2000 of whole-grain filler was about 2.1 Mt and of ground silica for filler was 159,000 t.

Cristobalite, a high-temperature silica mineral, is made from quartz by heating quartz to above 1,470° C. It consists of small octahedral crystals, which aggregate into rounded particles. The crystal structure is more open than quartz, resulting in lower specific gravity. The major market for cristobalite is in the solid mold industry, but it is also used in ceramics, grinding products, reflective coatings, refractories, and traffic paints (Paint and Coatings Industry, 1997).

Sodium silicate, produced primarily by reacting sand and soda ash in a furnace, is one of the traditional chemicals made with silica sand. One of the forces driving the increased demand for sodium silicate is the zeolite industry, which uses sodium silicate in its synthetic zeolite production.

Potassium silicate is produced in a similar fashion to sodium silicate but uses potassium carbonate or potassium hydroxide. Potassium silicate is more expensive than sodium silicate and is used primarily in welding rods.

Specialty silicas are usually produced by means of chemical and thermal processing of natural silica, silicon metal, or as a byproduct of other mineral or chemical processing. Although the USGS does not specifically collect information for specialty silicas, consumption does affect natural silica sales. Specialty silicas and silanes (silica chemicals) include colloidal silicas, fumed silica, fused silica and quartz, organofunctional silanes, precipitated silica, silica gels, silicones, and ultra-high-purity silica. These silicas are used in a variety of industries and products, including abrasives, adhesives, beverages, catalysts, coatings, electronics, encapsulants, food, health care, optics, paper and packaging, plastics, refractories, rubber, sealants, specialty coatings, textiles, thermoplastics, wafer polishing, and water treatment.

Pyrogenic, or fumed, silica forms tridimensional polymers used as thixotropic agents and in silicons and silanes and is widely used as a coating agent for filler-grade calcium carbonate (Industrial Minerals, 1998d). In table 6, industrial sand and gravel that would find its way into these specialty silicas is most likely reported by the producers in the categories "Chemicals," "Silicon metal," and possibly "Glassmaking: specialty." In 2000, silica sales for chemical production were 723,000 t, a decrease of 4.6% compared with those of 1999. Reported sales of silica gravel for silicon and ferrosilicon production increased by about 7% in 2000 compared with those of 1999. The main uses for silicon metal are in the manufacture of silanes and semiconductor-grade silicon and in the production of aluminum alloys.

Optical fiber production involves a series of highly sophisticated manufacturing methods. For the optical fiber, a glass core is required with a high refractive index, surrounded by glass with a lower refractive index. This problem has been solved by using several manufacturing methods, such as producing all the fiber with fused silica but doping its core with an element that increases the refractive index (Industrial Minerals, 1998c).

High-purity fused silica used by the electronics industry is typically at least 99.95% SiO_2 and has a very low expansion coefficient, high electromagnetic radiation transparency, and good insulation properties.

By reacting sodium silicate with hydrochloric acid, synthetic precipitated silica and silica gel are produced. Precipitated silica has been used increasingly in tires but more so in Europe than in the United States. Through replacement of a proportion of carbon black with precipitated silica in the tread, the reinforcing action of the silica particles extends tire life (Industrial Minerals, 2000a). European consumers seem to prefer the "green" tires made with precipitated silica, and it is used in 70% to 80% of tires for passenger cars (Industrial Minerals, 2000b). Although these tires reportedly produce greater gas mileage, deficiencies in tread wear and higher costs to consumers and manufacturers account for their lack of popularity in the United States. Some new silicas, which aim to alleviate these problems, are being produced. If these problems are solved, then the "green" tire will probably become more popular in the United States. Precipitated silica is also used in battery separators and as a flatting agent in coatings, mainly high-solid, low-volatility organic compound coatings.

Transportation.—Of the total industrial sand and gravel produced, 61% was transported by truck from the plant to the site of first sale or use, down from 62% in 1999; 36% was transported by rail, up from 35% in 1999; 3%, by waterway; and 1% was not transported. Because most of the producers did not report shipping distances or cost per metric ton per mile, transportation cost data are not available.

Prices.—Compared with the average value of 1999, the average value, free on board (f.o.b.) plant, of U.S. industrial sand and gravel increased by 4.7% to $19.57 per metric ton in 2000 (table 6). The average unit values for industrial sand and industrial gravel were $19.87 per ton and $14.69 per ton, respectively. The average price for sand ranged from $6.50 per ton for metallurgical flux to $114.62 per ton for ground fillers. For gravel, prices ranged from $8.97 per ton for nonmetallurgical flux to $23.36 per ton for filtration. Producer prices reported to the USGS for silica commonly ranged from

Digitized by Google

several dollars to hundreds of dollars per metric ton, and occasionally prices exceeded the $1,000-per-ton level. Nationally, ground sand used as fillers for rubber, paint, and putty had the highest value per metric ton ($114.62), followed by silica for swimming pool filters ($68.29), ground sand for ceramics ($51.94), ground sand for fiberglass ($43.05), ground sand for scouring cleansers ($37.47), refractory foundry sand ($36.11), abrasives for sawing and sanding ($35.56), and sand for hydraulic fracturing ($34.75).

Industrial sand and gravel price changes were mixed; some markets remained level, others had small increases or decreases, and still others had large increases or decreases. Although the silica was essentially the same, this situation was possible because most markets were independent of each other, and price competition was influenced by availability, regulations, health concerns, and competition from other materials.

By geographic region, the average value per ton of industrial sand and gravel was highest in the West ($21.38), followed by the South ($21.15), the Northeast ($20.60), and the Midwest ($17.29) (table 6). Prices can vary greatly for similar grades of silica at different locations in the United States. For example, the average value per ton of glass sand varied from $20.02 in the West to $14.98 in the Midwest. Tighter supplies and higher production costs in the West and much greater competition in the Midwest caused the difference in the cost of sand and gravel in these two regions.

Destination of Shipments.—Producers of industrial sand and gravel were asked to provide statistics on the destination of silica produced at their operations. The producers were asked to list only the quantity of shipments (no value data were collected in this section) and to which State or other location the material was shipped for consumption. Because some producers did not provide this information, their data were estimated or assigned to the "Destination unknown" category. In 2000, 9.7% of industrial sand and gravel shipped by producers was assigned to the "Destination unknown" category.

The States receiving the most industrial sand and gravel were, in descending order, Texas (7.1%), Illinois (6.7%), California (6.3%), Ohio (5.6%), Pennsylvania (4.9%), and Michigan (4.7%). With the exception of Alaska, all States received industrial sand and gravel. Producers reported sending at least 934,000 t of silica to Canada and 195,000 t to Mexico (table 7).

Foreign Trade.—Based on U.S. Census Bureau data, exports of industrial sand and gravel in 2000 decreased by 0.6% compared with the amount exported in 1999, and the associated value increased by about 35% (table 8). Most of the decrease in exports was attributable to decreased shipments to Mexico and Canada. For the fourth consecutive year, Mexico was the largest recipient of U.S. exports. Export distribution was as follows: 37% to Mexico, 28% to Asia, 19% to Canada, 11% to Europe, and the remainder to Africa, the Middle East, Oceania, and South America. The average price per ton of exports rose to $108 in 2000 from $80 in 1999. The increase in price reflected increased exports of higher grade silica, which averaged about $242 per ton, to Europe. Excluding Europe, other exports averaged $91 per ton in 2000.

The U.S. Census Bureau also reported that imports for consumption of industrial sand and gravel rose to 247,000 t, an increase of 17% from imports in 1999 (table 9). Silica imports vary greatly from year to year but are always rather insignificant in relation to total consumption. Canada supplied 73% of the silica imports for 2000, averaging about $12 per ton (including insurance and freight cost to the U.S. port). The total value of imports was $11.8 million, with an average of $48 per ton. Higher priced imports came from Australia, China, Germany, and Japan.

World Review.—Based on information provided mainly by foreign governments, world production of industrial sand and gravel was estimated to be 96 Mt. The United States was the leading producer, followed in descending order by Germany, Austria, Spain, and France. Most countries in the world had some production and consumption of industrial sand and gravel, which is essential to the glass and foundry industries. Because of the great variation in reporting standards, however, obtaining reliable information was difficult. In addition to the countries listed, many other countries were thought to have had some type of silica production and consumption (table 12).

Outlook.—The forecast range of total U.S. demand for industrial sand and gravel in 2001 is 28 to 30 Mt. Demand is expected to be about 29 Mt. All forecasts are based on previous performances for this commodity within various end uses, contingency factors considered relevant to the future of the commodity, and forecasts made by analysts and producers in the various markets.

Sales of glass sand are expected to vary from market to market. Growth that might come in some segments, such as flat and specialty glass, will be offset by reductions in sales for container glass and possibly fiberglass. The trend towards the decreasing market share for container glass in the United States is expected to continue.

Total demand for glass sand is expected to grow slowly through 2001, probably to the range of 10 to 12 Mt.

The demand for foundry sand is dependent mainly on automobile and light truck production. Another important factor for the future consumption of virgin foundry sand is the recycling of used foundry sand. The level of recycling, though not clear, is thought to be increasing. Other materials or minerals compete with silica as foundry sand, but these other "sands" usually suffer a severe price disadvantage. On the basis of these factors, consumption of silica foundry sand in 2001 is expected to be 6.3 Mt, and the demand range is expected to be 6 to 7 Mt.

Frac sand sales declined by about 4% in 2000, compared with those of 1999. Domestic crude oil prices fluctuated during 2000, and domestic crude oil production was down from 1999 levels. On the basis of these factors, demand for frac sand is expected to remain about level during 2001. Demand for frac sand in 2001 is expected to be 1.4 Mt, with a range of 1.3 to 1.5 Mt.

For specialty silicas, the source of the silica is usually through the chemical and silicon metal categories, which will probably see better-than-average growth, in the 2%- to 4%-per-year range. This positive forecast would be tempered if the specialty silicas producers use a silica source other than industrial sand and gravel. Because the process for each type of silica is highly variable and certainly not well advertised, determining the natural source and the processing method for each of the silicas or silicates is difficult.

Specialty silicas are increasingly recognized as having reinforcing properties as fillers in various manufactured products. The average growth of specialty silicas in the United States is about 4% per year. Consumption in 2003 is expected

Digitized by Google

to be 35,000 t of fumed and precipitated silica fillers (Industrial Minerals, 1998b). Another forecaster also projects 4% per year growth for specialty silicas, with fastest growth for fumed silica at 5%, precipitated and colloidal silica at 4%, and silica gel at 3.5% (Chemical Market Report, 1998).

The United States is the largest producer and consumer of silica sand and is self-sufficient in this commodity. Most of it is produced at premier deposits and near major markets in the Eastern United States. A significant amount of silica sand is also produced in the West and Southwest, mostly in California and Texas. Domestic production is expected to continue to meet more than 99% of demand well beyond 2001. Imports, mostly from Australia, Canada, and Europe, are expected to remain minor.

Because the unit price of silica sand is relatively low, except for a few end uses that require a high degree of processing, the location of a silica sand deposit in relation to the market is an important factor that may work for or against a sand producer. Consequently, a significant number of relatively small operations supply local markets with a limited number of products.

Several factors could affect supply and demand relations for silica sand. Further increases in the development of substitute materials for glass and cast metals could reduce demand for foundry and glass sand. These substitutes, mainly polymers and ceramics, would likely increase the demand for ground silica, which is used as a filler in plastics; for glass fibers, which are used in reinforced plastics; and for silica (chemical, whole grain, or ground), which is used to manufacture ceramics. Also, increased efforts to reduce waste and to increase recycling could hinder demand for glass sand. With advances in high-tech materials and specialty silicas, however, consumption of silica sand may increase for fiberoptics and other silicon and glass compounds. Although developments could cause demand for silica sand to decrease, the total value of production could increase because of the increased unit value of the more specialized sands.

Health concerns about the use of silica as an abrasive and stricter legislative and regulatory measures concerning silica exposure could reduce demand in many silica markets. The use of silica sand in the abrasive blast industry was being questioned as a health hazard, as marketers of competing materials, including garnet, olivine, and slags, pushed use of their "safer" abrasive media.

Development of more efficient mining and processing methods is expected to continue. This will encourage the development of lower grade silica sand deposits that are located closer to markets but are not presently mined. Such developments are expected to increase silica sand reserves.

Quartz Crystal

Electronic-grade quartz crystal is single-crystal silica with properties that make it uniquely useful for manufacturing accurate frequency controls, timers, and filters in electronic circuits. These devices are used for a variety of electronic applications in aerospace hardware, communications equipment, computers, consumer goods (e.g., clocks, games, television receivers, and toys), and military and commercial navigational instruments. Such uses generate practically all demand for electronic-grade quartz crystal. A lesser amount of optical-grade quartz crystal is used as lenses and windows in specialized devices, including some lasers.

Natural quartz crystal primarily was used in electronic and optical applications until 1971, when it was surpassed by cultured quartz crystal. The use of natural quartz crystal for carvings and other gemstone applications has continued. The use of quartz crystal for such applications is covered in the gemstones chapter of the USGS Minerals Yearbook.

Legislation and Government Programs.—The strategic value of quartz crystal was demonstrated during World War II when it gained wide use as an essential component of military communication systems. After the war, natural electronic-grade quartz crystal was officially designated as a strategic and critical material for stockpiling by the Federal Government. Cultured quartz crystal, which eventually supplanted natural crystal in nearly all applications, was not commercially available when acquisition of the latter for a national stockpile began.

As of December 31, 2000, the National Defense Stockpile (NDS) contained about 105,309 kilograms (kg) of natural quartz crystal with a reported market value of about $696,000. The stockpile has 11 weight classes for natural quartz crystal ranging from 200 grams to more than 10,000 grams. The stockpiled crystals, however, are primarily in the larger weight classes. The larger pieces are suitable as seed crystals to produce cultured quartz crystal. In addition, many of the stockpiled crystals could be of interest to the specimen and gemstone industry. Little, if any, of the stockpiled material is likely to be used in the same applications as cultured quartz crystal.

As cultured quartz crystal displaced natural quartz crystal in most applications, the Federal Government continued to assess its stockpile goals for the latter material. In the latest reports on the inventory of stockpile material, no quartz crystals were designated for disposal. No natural quartz crystal was sold in 2000. Previously, only individual crystals in the NDS inventory that weighed 10 kg or more and could be used as seed material were sold. Brazil traditionally has been the source of such large natural crystals, but changes in mining operations have reduced its output.

Quartz crystal, a form of crystalline silica, is also affected by the regulation of crystalline silica as discussed in the legislation and government programs subsection of the industrial sand and gravel section of this review.

Production.—The USGS collects production data for quartz crystal through a survey of the domestic industry. In 2000, the industry consisted of three cultured quartz crystal producers. One of the growers responded to the annual survey, and the other two were estimated based on previously reported figures.

The following U.S. companies produced cultured quartz crystal during 2000: Sawyer Research Products Inc. of Eastlake, OH; Thermo Dynamics Corp. of Merriam, KS; and CTS Corp. of Carlisle, PA. P.R. Hoffman Material Processing Co. of Carlisle, PA, has the capacity to produce cultured quartz crystal but had no production in 2000. Sawyer and Thermo Dynamics produced crystal bars for domestic and foreign firms in the crystal device fabrication industry. CTS produced quartz crystal for internal consumption and domestic device fabricators.

The above-mentioned companies produced cultured quartz crystal by using a hydrothermal process in large pressure vessels known as autoclaves. Seed crystals (very thin crystals cut to exact dimensions) are mounted on racks and suspended in

Digitized by Google

the upper growth region of the vessel. Lascas, a high-purity natural quartz feedstock, is loaded in an open-mesh wire basket that is placed in the bottom of the autoclave. A solution of sodium hydroxide or sodium carbonate (the mineralizer) with such additives as lithium salts and deionized or distilled water is used to fill the vessel from 75% to 85% of its volume. The bottom half of the growing vessel is heated to temperatures averaging between 350° C and 400° C; the temperature of the top portion is maintained at 5° C to 50° C less, depending upon the mineralizer used. At these temperatures, the solution expands and creates internal pressure between 700 and 2,100 kilograms per square centimeter. Under these conditions, the lascas dissolves to create a solution saturated with silica. Through convection, the saturated solution transports dissolved silica to the cooler upper half of the vessel where it becomes supersaturated, and the excess dissolved quartz deposits on the seed crystals in the top half of the autoclave. The process continues until the growing crystals reach their desired size. The process normally takes from 30 to 60 days for a 1-inch-thick bar and longer for other types of crystal; at least one producer has made runs of about 180 days. The cultured crystals can be custom grown with specific properties.

Processing quartz crystal for various end uses is the same whether natural or cultured seed crystal is used. Producers, however, must avoid seed crystals with defects that could be passed on to new generations of cultured crystal. Natural quartz crystal is preferred as seed material to ensure that genetic defects will not be repeated in the succeeding generations.

Once produced, cultured crystals are examined for physical defects before cutting. They are then cut, usually with diamond or slurry saws, along a predetermined crystallographic plane to a thickness slightly larger than that desired. Each wafer is inspected and diced into blanks of the desired dimensions. The blanks then progress through a series of lapping stages until they reach the final thickness, electrodes are then attached, and the crystals are mounted in suitable holders. The final assembly, called a quartz crystal unit, is ready for insertion into an electronic circuit.

Consumption.—In 2000, the USGS collected domestic consumption data for quartz crystal through a survey of 26 U.S. operations in 9 States that fabricate quartz crystal devices. These operations represented virtually all the domestic consumption. Of the 26 operations, 18 responded to the survey. Consumption for nonrespondents was estimated based on reports from previous years.

Quartz crystal is used in piezoelectric and optical applications. The piezoelectric effect is achieved when a suitable electrical signal applied to a quartz wafer makes the wafer vibrate mechanically throughout the bulk of the material at a characteristic natural resonance frequency. Quartz resonators are uniquely suitable for aerospace, commercial, and military bandpass filter applications that require very high selectivity or for oscillator applications that require very high stability. In addition, for many applications requiring only moderate stability, a quartz resonator offers a unique combination of high performance, small size, and low cost. Quartz resonators also are used for many less demanding applications, such as providing timing signals for electronic circuits in automotive, consumer, and industrial products.

Cultured quartz is used almost exclusively by the crystal device industry because of the cost advantages. For resonator applications, raw cultured quartz must be cut into thin wafers oriented precisely with the raw material crystal axes. The uniformity and convenience of cultured quartz have made its use almost universal. Unlike cultured quartz, natural electronic-grade quartz requires special orientation, cutting, grading, and sizing to produce a quartz wafer. As a result, most device manufacturers that cut natural quartz in the past have discontinued its use. One of the remaining applications of the natural electronic-grade material is in pressure transducers used in deep wells.

Quartz wafers must be cut too thinly for practical use at very high frequencies (above 100 megahertz). Quartz crystal structures that use surface vibrations, in which the frequency is determined by electrode dimensions rather than by wafer thickness, have become more prevalent at these higher frequencies. These structures are called surface acoustical wave devices.

Most optical applications use quartz in the fused form as silica glass. Relatively small quantities of cultured quartz crystal are used directly in optical applications. Quartz crystal also has uses involving birefringent filters, Brewster windows and prisms, normally polarized laser beams, quartz retardation plates (especially quartz wave plates), and tuning elements in laser optics.

Prices.—The average value of as-grown cultured quartz was estimated to be about $23 per kilogram in 2000. The average value of lumbered quartz, which is as-grown quartz that has been processed by sawing and grinding, was estimated to be about $143 per kilogram. As noted above, the estimated average market value of the unprocessed quartz crystal in the NDS in 2000 was about $7 per kilogram.

Foreign Trade.—The U.S. Department of Commerce (DOC), which is the major Government source of U.S. trade data, does not provide specific import or export statistics on lascas. Some lascas was imported from Germany in 2000, according to some consumers. Imports and exports of all electronic-grade quartz crystal are listed in table 11.

World Review.—Cultured quartz crystal production is concentrated in China, Japan, Russia, and the United States, with several companies producing crystal in each country. Production is less in Belgium, Brazil, Bulgaria, France, Germany, South Africa, and the United Kingdom. Details concerning quartz operations in China, Eastern European countries, and the nations of the former Soviet Union are unavailable. Operations in Russia, however, have significant capacity to produce synthetic quartz.

Outlook.—Because the demand for quartz crystal devices will probably continue to grow, quartz crystal production will probably remain strong well into the future. The trend towards importing quartz could have a negative effect on domestic quartz growers. Growth of the consumer electronics market (e.g., automobiles, cellular telephones, electronic games, and personal computers), particularly in the United States, will continue to provide consumer outlets for domestic production. The growing global electronics market may require additional production capacity worldwide.

Special Silica Stone Products

Silica stone products are materials for abrasive tools, such as deburring media, grinding pebbles, grindstones, hones,

Digitized by Google

oilstones, stone files, tube-mill liners, and whetstones. These products are manufactured from novaculite, quartzite, and other microcrystalline quartz rock. This chapter, however, excludes products that are fabricated from such materials by artificial bonding of the abrasive grains. Information on other manufactured and natural abrasives may be found in other USGS Minerals Yearbook chapters.

Special silica stone, a crystalline silica, is also affected by the regulation of crystalline silica, as discussed in the legislation and government programs subsection of the industrial sand and gravel section of this review.

Production.—In response to a USGS production survey, 9 of 10 domestic firms reported that they quarried certain silica materials and manufactured silica stone products during 2000. Data for the remaining producer were estimated. Arkansas accounted for most of the value and quantity of production reported. Plants in Arkansas manufactured files, deburring-tumbling media, oilstones, and whetstones. Tumbling-grinding media were produced in Wisconsin (table 10).

The industry has produced four main grades of Arkansas whetstone in recent years. The grades range from the high-quality black hard Arkansas stone down to Washita stone. In general, the black hard has a porosity of 0.07% and a waxy luster, and Washita stone has a porosity of 16% and resembles unglazed porcelain.

Consumption.—The domestic consumption of special silica stone products is a combination of craft, household, industrial, and leisure uses. Major household uses include the sharpening of knives and other cutlery, such as lawn and garden tools, scissors, and shears. Leading industrial uses include the deburring of metal and plastic castings, the polishing of metal surfaces, and the sharpening and honing of cutting surfaces. Recreational uses include the sharpening of arrowheads, fish hooks, spear points, and sports knives. Craft applications include sharpening tools for engraving work, jewelry making, and wood carving. Also, silica stone files are used in the manufacture, modification, and repair of firearms.

Price.—The average value of crude material suitable for cutting into finished products was $286 per ton. The average value of stone products made from crude material was $14.76 per kilogram.

Foreign Trade.—In 2000, silica stone product exports had a value of about $6.4 million, unchanged from that of 1999. These exports were categorized as "hand sharpening or polishing stones" by the DOC. This category accounted for most of, if not all, the silica stone products exported in 2000.

In 2000, the value of imported silica stone products was at least $3.8 million, down by 39% compared with that of 1999. These imports were hand-sharpening or polishing stones, which accounted for most of or all of the imported silica stone products in 2000. A portion of the finished products that were imported may have been made from crude novaculite produced within the United States and exported for processing.

Outlook.—Consumption patterns for special silica stone are not expected to change significantly during the next several years. Most of the existing markets are well defined, and the probability of new uses is low.

Tripoli

Tripoli, broadly defined, comprises extremely fine grained crystalline silica in various stages of aggregation. Grain sizes usually range from 1 to 10 micrometers, but particles as small as 0.1 to 0.2 micrometer are common. Commercial tripoli contains 98% to 99% silica and minor amounts of alumina (as clay) and iron oxide. Tripoli may be white or some shade of brown, red, or yellow depending upon the percentage of iron oxide.

Tripoli, a crystalline silica, is also affected by the regulation of crystalline silica as discussed in the legislation and government programs subsection of the industrial sand and gravel section of this review.

Production.—In 2000, five U.S. firms were known to produce and process tripoli. American Tripoli Co. produced crude material in Ottawa County, OK, and finished material in Newton County, MO. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale purchased from local suppliers. Malvern Minerals Co. in Garland County, AR, produced crude and finished material from novaculite. Harbison-Walker Refractories Co. Inc. in Hot Springs County, AR, produced crude and finished tripoli that is consumed in the production of refractory bricks and shapes. Unimin Specialty Minerals Inc. in Alexander County, IL, produced crude and finished material. All these firms responded to the USGS survey.

Consumption.—The 2000 USGS annual survey of producers indicates that sales of processed tripoli decreased by 15% in quantity to 72,000 t with a value of $15.9 million (table 1).

Tripoli has unique applications as an abrasive owing to its hardness and because its grain structure lacks distinct edges and corners. It is a mild abrasive, making it suitable for use in toothpaste and tooth-polishing compounds, industrial soaps, and metal- and jewelry-polishing compounds. The automobile industry uses it in buffing and polishing compounds for lacquer finishing.

The end-use pattern for tripoli has changed significantly in the past 30 years. In 1970, nearly 70% of the processed tripoli was used as an abrasive. In 2000, about 24% of tripoli output was used as an abrasive. The remainder was used as filler and extender in enamel, caulking compounds, paint, plastic, rubber, and in brake friction products, linings, refractories, and other products.

The primary use of tripoli today is as a filler and extender in paints. These applications may account for as much as 85% of the tripoli used as a filler and extender. In exterior latex paints, tripoli also aids in durability, flowability, leveling, and tint retention. In enamels, it eases application and improves sheen. The controlled grain and particle size of tripoli in paints improves dispersal and promotes a more uniform coating. Additionally, paints with tripoli resist chemical agents and wear better than those in which water-ground whitings and other softer or more reactive fillers are used.

Plastics, resins, and rubbers each account for about 5% of the tripoli used as a filler and extender. Tripoli is used extensively in plastics for electrical uses because of its dielectric characteristics and its effects on compression and flexibility properties. Its chemical resistance, resistance to salt spray, and weatherability also are important to its use in plastics. The physical properties of tripoli allow high loading in most compounds, but its abrasiveness results in high wear in extruding nozzles and molds. The same properties that make tripoli useful as a filler and extender in plastic make it valuable

Digitized by Google

to the rubber and resin industries.

Price.—The average reported value of all tripoli sold or used in the United States was $221 per ton in 2000. The average reported value of abrasive tripoli sold or used in the United States during 2000 was $183 per ton; the average reported value of filler tripoli sold or used domestically was $265 per ton.

Outlook.—Consumption patterns for tripoli are not expected to change significantly during the next several years. Most of the existing markets are well defined, and the probability of new uses is low.

SILICON

By Thomas S. Jones

Domestic survey data and tables were prepared by Lisa D. Miller, statistical assistant.

Silicon (Si) is a light chemical element with metallic and nonmetallic characteristics. In nature, silicon combines with oxygen and other elements to form silicates. Silicon in the form of silicates constitutes more than 25% of the Earth's crust. Silica is a silicate consisting entirely of silicon and oxygen. Silica (SiO_2) as quartz or quartzite is used to produce silicon ferroalloys for the iron and steel industries, and silicon metal for the aluminum and chemical industries. Ferrosilicon and silicon metal are referred to by the approximate percentage of silicon contained in the material and the maximum amount of trace impurities present.

Almost all ferrosilicon products are consumed by the iron and steel industries. In terms of their nominal silicon contents, the two standard grades of ferrosilicon are 50% ferrosilicon and 75% ferrosilicon.

Silicon metal is used by the primary and secondary aluminum industries and the chemical industry, which uses it principally for silicones. Specifications for silicon metal used by the primary aluminum and chemical industries generally are more stringent than those for metal used by the secondary aluminum industry. In addition, the chemical industry requires that the metal be ground into a fine powder rather than the lump form used by the aluminum industry. Silicon metal that is refined into semiconductor-grade metal for use in making computer chips is crucial to modern technology, but the quantity is less than 5% of total silicon metal demand (Roskill's Letter from Japan, 2000). This report contains no information about this highest purity silicon except as it appears in the foreign trade statistics.

For 2000, an overall domestic silicon production of 367,000 metric tons (t) of contained silicon was the least since 1993. Decreases in production and shipments were the most notable in the ferrosilicon category of 56% to 95% silicon content (nominal 75% ferrosilicon), for which the declines were about 30%. On the basis of contained silicon, overall U.S. trade volumes rose by about 26% for imports and decreased by about 33% for exports. The trade category corresponding to nominal 75% ferrosilicon accounted for the majority of imports and increase in import volume. The export decline was associated mostly with silicon metal. The combination of decreased domestic production with increased net imports resulted in record high apparent consumption levels for ferrosilicon, silicon metal, and silicon materials overall; for silicon overall, the increase was 7% to 689,000 t. U.S. net import reliances for silicon materials equaled or exceeded any previous values, rising overall to 47% from 34%. Year-average dealer import prices for standard grades of ferrosilicon and silicon metal decreased for the fourth successive year, by a range of 8% to 12% for ferrosilicon and 6% for metal.

Legislation and Government Programs

The fine of $150,000 given in 1998 to the then-SKW Metals and Alloys Inc. (became CC Metals and Alloys, Inc., in 1999) for ferrosilicon price fixing was upheld in July by the presiding judge for the original criminal trial (Ryan's Notes, 2000c). The amount of the fine subsequently was appealed again by the U.S. Department of Justice (Ryan's Notes, 2000d). The fine being contended had been set by the U.S. District Court for the Western District of New York in Buffalo, NY.

Production

In terms of gross weight and in comparison with those of 1999, overall domestic gross production, net shipments, and stocks of silicon products decreased by about 13%, 16%, and 2%, respectively. The most pronounced year-to-year percentage declines were for the ferrosilicon category of 56% to 95% silicon content (nominal 75% ferrosilicon), for which

Silicon in the 20th Century

Usage of silicon as a ferroalloy in the production of steel and cast iron had been established prior to the turn of the century. Silvery pig iron, a low content silicon ferroalloy generally containing less than 20% silicon, already had been produced using blast furnaces in the 1890s. Electric furnace technology for producing silvery pig iron, ferroalloys with higher nominal silicon contents between 50% and 75%, and silicon metal began to be developed beginning about the start of the 20th century. Production and use of silicon ferroalloys received considerable impetus from World Wars I and II; use of ferrosilicon can be estimated to have paralleled domestic raw steel production, which increased approximately by a factor of 7.5 during the century.

The first significant use developed for silicon as a bulk element was for alloying with aluminum around 1920. After aluminum castings, the second largest use for silicon was production of silicones and related chemicals, which began developing in the 1930s and was accelerated during World War II. A third development, which began shortly after World War II, was usage of relatively small amounts of silicon in high-value, high purity forms in such key electronic devices as computer chips.

In 2000, U.S. production of the various grades of ferrosilicon plus elemental silicon (commonly referred to as metal) was about 400,000 metric tons of silicon content valued at approximately $400 million. Worldwide, in terms of gross weight, production was about 4 million metric tons for ferrosilicon and about 900,000 tons for silicon metal.

Digitized by Google

production and shipments fell by about 30%. For silicon metal, production and shipments decreased by about 6% and 8%, respectively; stocks decreased only marginally. These comparisons are exclusive of silvery pig iron, statistics for which were not published to avoid disclosing proprietary data. In terms of silicon content and also exclusive of silvery pig iron, overall production of silicon materials was the least since 1993.

Domestic production data for silicon are derived from monthly and annual voluntary surveys and estimates for nonrespondents by the U.S. Geological Survey (USGS). The figures in table 2 represent 100% of the production and shipments from the operations listed in table 3 that are canvassed by means of the Silicon Alloys survey.

American Alloys Inc. stopped production of ferrosilicon and foundry alloys at its Graham, WV, plant after suddenly having declared Chapter 11 bankruptcy on January 26. Low prices and removal of antidumping duties on ferrosilicon from a number of foreign countries appeared to have been among the factors resulting in American Alloys' shutdown (Ryan's Notes, 2000a). This was the second time within 5 months that production was stopped at a domestic smelter where silicon ferroalloys or metal was being produced. After the shutdown, American Alloys sold material in inventory and manufacturing equipment (Platt's Metals Week, 2000; Ryan's Notes, 2000f).

Globe Metallurgical, Inc., with headquarters in Cleveland, OH, already a part owner of Norway's Fesil ASA, made an offer in August for all of the outstanding shares of Fesil, a producer of ferrosilicon and silicon metal (Ryan's Notes, 2000e). The offer was withdrawn early in November after it failed to interest holders of at least 90% of the outstanding shares (Metal Bulletin, 2000).

At Simcala, Inc. unionized hourly workers went on strike as of August 8. No immediate effect of the strike was apparent at the company's silicon metal plant at Mount Meigs, AL, a short distance east of Montgomery, as the striking workers were only a part of the total workforce (Ryan's Notes, 2000i). The strike continued for the rest of the year.

Principal elements in the cost of silicon and ferrosilicon production are the delivered costs of the ore (quartz or quartzite) and costs of energy, reductant coke or low ash coal, iron in the form of steel scrap (if required), and labor. Production of silicon metal and silicon-containing alloys is extremely power intensive and can require up to 14,000 kilowatthours of electric energy per metric ton of silicon contained in the final product (Dosaj, 1997, p. 1105). This high-energy demand can be offset somewhat by recovering heat energy from furnace offgases. Locations of ferrosilicon and silicon metal smelters are usually determined by balancing marketing costs against processing costs.

Silicon is not generally recovered from secondary sources. The only secondary possibility is recovery from metallic scrap, such as aluminum alloys, cast iron, and steel, from which recovery of contained silicon is incidental to that of the primary metal. Some silicon is recycled internally in smelters when fines or offgrade material are remelted.

Consumption

Ferrosilicon was used primarily as a deoxidizing and alloying agent in the production of iron and steel products. Silicon metal, which can be classified into metallurgical and chemical grades, was used by the aluminum industry in the production of cast and wrought products. It also served as the basic raw material in the manufacture of many chemical products and intermediates, such as silicones and silanes. Small quantities of silicon were processed into high-purity silicon for use in the semiconductor industry.

For 2000, total U.S. apparent consumption of silicon-containing ferroalloys and silicon metal was estimated to have increased by about 7% to 689,000 t of contained silicon. Also in terms of contained silicon, apparent consumption increased about 6% to 397,000 t for ferrosilicon and miscellaneous silicon alloys and somewhat more than 8% to 292,000 t for silicon metal. Increases in net imports that outweighed decreases in production resulted in the above three figures for apparent consumption that are thought to be the greatest ever. Still on the basis of silicon content, the share of total demand accounted for by ferrosilicon and miscellaneous silicon alloys remained at 58%. Table 4 presents data on U.S. reported consumption and stocks of silicon materials in 2000.

One supplier of ferroalloys has estimated that its shipments to iron foundries that consisted mostly of magnesium ferrosilicon, inoculants, and standard grades of ferrosilicon have advanced at a combined annual growth rate (CAGR) of 18% between 1992 and 1999 (Ryan's Notes, 2000k). Future growth in shipments to foundries appears likely to be slowed by plans by at least one domestic automobile manufacturer to replace iron by aluminum in engines (Wrigley, 2000).

Particularly in iron foundries, metallurgical-grade silicon carbide can substitute for ferrosilicon. Data on North American production and U.S. imports of silicon carbide were reported in the 2000 annual review of Manufactured Abrasives in the Mineral Industry Surveys series of the USGS and in the Manufactured Abrasives chapter of the 2000 Minerals Yearbook.

Consumption of ferrosilicon and silicon metal was estimated by CRU International Ltd. to have increased in 2000 for all areas of the Western World. In terms of contained silicon, the increase overall was from 1.73 million metric tons (Mt) to 1.83 Mt for ferrosilicon, and from a revised figure of 928,000 t to 1.03 Mt for silicon metal. The 2000 total for silicon metal consumption was the second consecutive alltime high. Areas having the largest year-to-year percentage increases were, for ferrosilicon, Japan and Other Asian countries, and for silicon metal, Japan and Western Europe. In decreasing order, Western Europe, Japan, and the United States accounted for 70% of the 2000 consumption total for ferrosilicon. Also in decreasing order, Western Europe, the United States, and Japan accounted for 84% of that for silicon metal (CRU Bulk Ferroalloys Monitor, 2001b).

For silicon wafers made from polycrystalline silicon, the CAGR between 1999 and 2003 has been forecast as about 10% (Hunter, 2000).

The CAGRs for silicone demand have been assessed as in excess of 10% for Southeast Asia, 4% to 6% for Western Europe and the United States, and 2% to 4% for Japan (Westervelt, 2000). Globally, the CAGR for silicones and silanes between 1995 and 1998 has been put at 6%. Consumption of silicones in the United States has been projected to have a CAGR of between 4% and 6% between 2000 and 2003 (Boswell, 2000). A healthy growth rate in demand also is forecast for silanes that function as coupling agents for fillers used in polymer composites. Sales of silane coupling agents worldwide currently amount to $600 million (Mack, 2000). Expansion of silicones operations overseas has

Digitized by Google

been viewed as presenting a challenge to U.S. producers of silicon metal that serves as feedstock for silicones production. As an example, Dow Corning Corp.'s expansion in Wales has caused Dow Corning's Carrollton, KY, silicones plant to become a "swing" producer (Ryan's Notes, 2000b, g).

Microsilica (silica fume) is a potential byproduct from furnaces making silicon metal or ferrosilicon with a silicon content of at least 75%. It is obtained by capturing furnace offgases and finds use as a binder and filler in cements. The amount of microsilica dust currently being generated from silicon metal furnaces per year worldwide can be estimated to exceed 300,000 t (Kendall, 2000).

Prices

Demand for silicon ferroalloys and metal is determined in the short term less by their prices than by the level of activity in the steel, ferrous foundry, aluminum, and chemical industries. As a result, prices tend to vary widely with changes in demand and supply. The basis for U.S. prices of silicon materials was cents per pound of contained silicon.

Year-average import prices, as given by Platt's Metals Week or as calculated from Platt's weekly listings, were, in cents per pound, 35.4 for 75% ferrosilicon and 54.8 for silicon metal; these prices were about 12% and 6% lower, respectively, than those of 1999. In 2000, yearend prices were lower than those at the beginning of the year by about 3% for 75% ferrosilicon and 5% for silicon metal. For 50% ferrosilicon, beginning in January and continuing through the first week of September, Platt's listed only a price range of 43 to 47 cents per pound, which was the same as at the end of 1999. After the first week of September, Platt's discontinued this price listing. For the 8 months of 2000 this listing was in effect, the average of 45 cents per pound for 50% ferrosilicon was about 8% less than that for all of 1999. The ranges for North American transaction price for 50% ferrosilicon as given by Ryan's Notes were nearly the same as the range given by Platt's. At the point at which Platt's discontinued its listing, Ryan's Notes gave, in cents per pound, 43 to 48, and at yearend, 42 to 48.

The decline in year-average prices for silicon materials continued for the fourth successive year. The year-average price for silicon metal again was the least of any year since 1990. For 75% ferrosilicon and silicon metal, the pattern of price changes was similar for each—a rising trend until the first of April, a plateau, and then an irregular downward trend for the rest of the year. The price range for 75% ferrosilicon, in cents per pound, began the year at 34 to 36.5, slightly below the range of 34 to 37 at the end of 1999, reached and maintained a plateau for 3 weeks at a high point of 37 to 39, and ended the year at 33 to 35.25. For silicon metal, the price range, in cents per pound, began the year at 52 to 53, the same as at the end of 1999, held for 8 weeks at a high point of 58 to 59, and ended the year at 49 to 51.

Causative factors cited by CRU International Ltd. for prices of 75% ferrosilicon that CRU regarded as the lowest ever in real terms included foreign exchange rates, abolition of U.S. antidumping duties, and world oversupply. Prices in the United States that were higher than those elsewhere led naturally to an influx of imports (CRU Bulk Ferroalloys Monitor, 2000). Besides the strong U.S. dollar, a drop in demand from the aluminum industry contributed to the price slide for silicon metal (Ryan's Notes, 2000h).

Foreign Trade

Compared with those for 1999, total volumes of ferrosilicon and silicon metal decreased for exports (-33%) and increased for imports (+26%), on a content basis. The biggest year-to-year changes were for exports of silicon metal and imports of ferrosilicon. On a content basis, overall imports seemingly were the highest ever for ferrosilicon and silicon metal.

U.S. exports of ferrosilicon decreased by about 7% overall in gross weight but increased by about 5% in value. Australia, Canada, India, Japan, the Republic of Korea, Mexico, and the United Kingdom were the recipients of about 90% of total 2000 exports of ferrosilicon (table 5). Exports of silicon metal decreased by 50% in gross weight but increased by about 19% in value. Shipments of high-purity silicon of high unit value that contained more than 99.99% silicon rose 45% to account for about 94% of total value. Shipments in the category of "silicon, other," were only about one-third as great as in 1999. Combined shipments to Canada, Germany, Japan, and Mexico accounted for about 78% of total shipments. Those to Mexico were only about one-fifth those in 1999.

U.S. imports of silicon ferroalloys increased overall by 31% in gross weight and 21% in value compared with those for 1999. Import volumes increased for all significant categories except for ferrosilicon containing 55% to 80% silicon and more than 3% calcium. About 86% of total quantity and 81% of total value were accounted for by imports of nominally 75% ferrosilicon (ferrosilicon category of "55% to 80% silicon, other") (table 6). Reflecting the removal of antidumping and countervailing duties on ferrosilicon in late 1999, this category had the greatest year-to-year percentage increase in volume (39%). Norway continued as the leading overall source of ferrosilicon, although its share of the total fell to 32%.

Overall imports of silicon metal increased by about 14% in volume and 6% in value compared with those for 1999. Imports in the category of "silicon content from 99.00% to 99.99%," displaced those of high-value silicon metal that contained more than 99.99% silicon, in accounting for the largest share of total value, about 45% versus 40%, respectively. Among imports with a silicon content of from 99.00% to 99.99%, import volumes increased by 72% for those from Brazil and by 62% for those from South Africa. For the category of "silicon content less than 99%," imports from Saudi Arabia were only about one-tenth those of 1999. The year-to-year percentage changes in import volumes were -7% for "silicon content more than 99.99%," +36% for "silicon content from 99.00% to 99.99%," and -18% for "silicon, other."

The quantities of silicon metal imported from China were perceived by industry sources to be significantly greater than shown in table 6 because of shipments purportedly via another country, such as the more than 8,000 t of material reported as having come from the Republic of Korea (CRU Bulk Ferroalloys Monitor, 2001a).

For 2000, U.S. net import reliances were estimated to have risen from 38% to 53% for ferrosilicon and from 29% to 38% for silicon metal. The overall import reliance for silicon was estimated to have increased from 34% to 47%. These import reliances for silicon materials are believed to surpass any previous values except that the percentage for silicon metal equals that for 1994.

The general rates of duty that applied to U.S. imports during

Digitized by Google

2000 were the same as in 1999. These were, on an ad valorem basis, 1.5% for standard 75% ferrosilicon, 1.1% for nominal 75% ferrosilicon that contains more than 3% calcium, free for magnesium ferrosilicon and most other ferrosilicon, and 5.3% or 5.5% for metal exclusive of the high-purity grade (U.S. International Trade Commission, 1999).

Effective with publication of Presidential Proclamation 7388 on December 21, the Generalized System of Preferences (GSP) Program was modified so as to grant duty-free status to certain products from sub-Saharan African countries. Ferrosilicon containing either 80% to 90% silicon or more than 90% silicon were among the products to which this form of GSP treatment now applied (Clinton, 2000). Silicon metal declarable under the import category that specifies a silicon content of less than 99% also had been a candidate for GSP treatment, but its tariff status was not changed (Ryan's Notes, 2000j).

The International Trade Administration (ITA) of the U.S. Department of Commerce published the results of its final or amended final antidumping duty administrative reviews for silicon metal from Argentina and Brazil.

For silicon metal from Argentina, for the period of review (POR) of September 1, 1997, through August 31, 1998, in a review that was specific only to Electrometalurgica Andina S.A.I.C. (Andina), it was found that no sales were made below normal value, so that no antidumping duties were assessed. Margins remained unchanged for other firms not covered in this review, as did the "all other" rate of 17.87% (International Trade Administration, 2000c). The ITA also rescinded its review for the POR of September 1, 1998, through August 31, 1999, for Andina because Andina made no shipments to the United States during this POR (International Trade Administration, 2000b).

For silicon metal from Brazil, for the POR of July 1, 1992, through June 30, 1993, the ITA amended again its final results for Companhia Brasileira Carbureto de Calcio (CBCC) and Eletrosilex Belo Horizonte to margins of 35.43% and 51.84%, respectively. These rates, however, did not change the cash deposit rates in effect for CBCC and Eletrosilex at the time of this amendment, as those rates continued to be based on the margins found in the most recently completed review (International Trade Administration, 2000e). For the POR of July 1, 1997, through June 30, 1998, the ITA determined a margin of 0.05% for CBCC; 18.87% for Eletrosilex; zero for Ligas de Aluminio, S.A., and Rima Industrial S/A; and 91.06% for "all others." The rate for CBCC was effectively zero because of its de minimis character of being less than 0.5% (International Trade Administration, 2000a).

The ITA also concluded expedited 5-year ("sunset") reviews of the antidumping duty orders on silicon metal from Argentina and China. The ITA found that revoking these orders was likely to lead to continuation or recurrence of dumping at weighted-average margins of 17.87% for Argentina and 139.49% for China (International Trade Administration, 2000d, f).

World Review[1]

Data on annual world production of ferrosilicon and silicon metal by country during 1996 to 2000 are given in Fenton [in press (a)]. World production of ferrosilicon was estimated to have been about 4.3 Mt in 2000 compared with a revised total of about 3.9 Mt in 1999. The major producers of ferrosilicon in 2000 were, in decreasing order, China, Russia, Norway, Ukraine, the United States, Brazil, Kazakhstan, France, and South Africa, and accounted for about 85% of total production. World production of silicon metal, excluding that from China, was estimated to have been about 720,000 t in 2000 compared with a revised total of about 700,000 t in 1999. China's production is believed to have been the world's largest, but data are lacking. Available information indicates that China's annual output of silicon metal in recent years was a minimum of 250,000 t (approximate export level) and, considering consumption within China, may have been in excess of 400,000 t. Other major producers of silicon metal in 2000 were, in decreasing order, the United States, Brazil, Norway, France, Russia, and South Africa; they accounted for about 82% of total production as listed in table 1.

Brazil.—In March, Dow Corning Corp. of the United States completed its acquisition of CBCC, which had an annual production capacity of 40,000 t for silicon metal and 20,000 t for ferrosilicon. Dow Corning planned to convert CBCC's facilities within a few years so as to give it the capability of producing 60,000 tons per year (t/yr) of silicon metal (Sissell, 2000). Subsequently, the structure of silicon metal production was changed further when Rima Industrial leased Eletrosilex' facilities having a silicon metal capability of 22,000 t/yr. Rima Industrial also was a producer of silicon as well as ferrosilicon.

Canada.—Bécancour Silicon Inc. described a new technology, termed the SKTEC process, by means of which either 75% ferrosilicon or silicon metal could be produced from the same furnace without any downtime in making a product change. This process has been in use continuously at Bécancour Silicon since late 1997 (Boisvert and Ksinsik, 2000).

China.—In 2000, China's exports of ferrosilicon rose to a total of about 490,000 t, and those of silicon metal totaled about 320,000 t. In 1999, exports of silicon metal exclusive of high-purity grades were 264,000 t, which was about 3% less than those of 1998; almost one-half of 1999 exports were reported to have gone to Japan.

A Government program for improving the efficiency and environmental performance of the country's electrometallurgical industries was underway. Production of ferrosilicon and silicon metal were among the materials to which this program applied, under which older and smaller furnaces were to be phased out.

France.—Invensil, formed in 1999 by combining the silicon metal activities of France's Pechiney Electrométallurgie (PEM) and South Africa's Samancor Ltd., enlarged its silicon capabilities in France and became wholly owned by Pechiney. In the first part of the year, a furnace at PEM's Château-Feuillet plant that was being used to produce calcium-silicon was converted to silicon metal, thus giving Invensil four production sites in France and adding 9,000 t to annual silicon production capacity. Late in the year, Pechiney acquired Samancor's minority interest in Invensil, thereby assuming full control of the Silicon Smelters plant at Pietersburg, South Africa.

India.—Late in the year, the Government recommended preliminary antidumping duties on imports of ferrosilicon from

[1]In a number of instances, discussions of the more significant developments during 2000 for specific countries were based on news items in trade journals, such as American Metal Market, Metal Bulletin, Platt's Metals Week, Ryan's Notes, and TEX Report. These items have not been acknowledged individually because the information they conveyed often was aggregated, possibly with that from other sources.

Digitized by Google

China and Russia, but not those from Iran. Dumping margins were determined as about 43% for Chinese material and about 57% for Russian material. The Government's investigation was in response to a petition from domestic ferroalloy producers.

Norway.—Approximately 1 year after Fesil ASA had stopped production of silicon metal from three furnaces in the first half of 1999, production was restarted from the two furnaces that still were idle. These were one each at the Holla Metall and Lilleby Metall plants. In November, the affiliation of Switzerland's Gurta AG and the U.K.'s Tensil Ltd. took control of Fesil from Globe Metallurgical of the United States. This change occurred after Globe withdrew an offer by means of which it sought at least 90% of Fesil's shares.

In late 2000, AstroPower Inc. of the United States and Elkem ASA formed a project under which a low-cost process was to be developed for manufacturing solar-grade silicon at a jointly owned plant to be built in Norway. The new plant was to be managed by Elkem and its construction was to begin within 2 years.

South Africa.—As mentioned under France, the Silicon Smelters plant at Pietersburg for production of silicon metal that was a part of Invensil came fully under the control of France's Pechiney.

Silicon Chemicals.—In May, Dow Corning celebrated completion of an expansion of capability for methylchlorosilanes (MCS) at its Barry, Wales, plant. That plant's annual production capacity for these intermediates for production of silicones was approximately doubled to almost 200,000 t (Chemical Week, 2000a). Projects elsewhere for increasing capabilities for production of silicon chemicals included a 30% expansion by Rhodia SA at its plant at Roussillon, France, that would raise by 2002 its capacity for MCS to 200,000 t/yr and for siloxanes to 100,000 t/yr (Chemical Week, 2000c). Also in Europe, the GE Bayer Silicones joint venture between GE Silicones (50.1% ownership) and Bayer AG planned to double by 2002 the MCS production capacity at the Leverkusen plant to 300,000 t/yr (Chemical Week, 2000b). GE Silicones and Japan's Shin-Etsu Chemical Co., Ltd., formed a joint venture to build a plant at a site to be selected in Southeast Asia that would have a production capacity of about 70,000 t/yr for siloxanes (Chemical Week, 2000d).

Current Research and Technology

Investigations relating to the smelting of ferrosilicon and silicon included use of petrographic analysis for selection of coals and cokes to be used as reductants (Buø, Gray, and Patalsky, 2000), determination of material balances for trace elements (Myrhaug and Tveit, 2000; Tveit and Myrhaug, 2000), and modelling of alternating current arcs during typical operating conditions (Sœvarsdottir, Bakken, Sevastyanenko, and Gu, 2000).

Laboratory investigations relating to the behavior of silicon in steelmaking systems included study of factors affecting the efficiency of ferrosilicon in reducing chromium oxide from stainless steelmaking slags (Lee, Rhee, Song, and Klevan, 2000) and a determination that silicon additions appreciably reduce the rate of nitrogen dissolution in molten iron (Morita, Hirosumi, and Sano, 2000).

With regard to applications for high-purity silicon, a silane-based process for producing solar-grade silicon from metallurgical-grade silicon was evaluated in the laboratory (Block and Wagner, 2000), and the surface tension of molten silicon was measured under conditions of microgravity (Fujii and others, 2000).

For the A356 aluminum casting alloy (nominally 7% silicon, 0.4% magnesium) commonly used in structural parts of automobiles, the mechanical behavior of silicon particles in the alloy was studied at the high strain rates associated with crashes (Dighe, Gokhale, Horstemeyer, and Mosher, 2000).

Outlook

Demand for ferrosilicon follows trends in the iron and steel industries, for which the CAGRs typically have been in the range of 1% to 2%. Details of the outlook for the steel industry are discussed in the Outlook section of the annual review for 2000 for Iron and Steel (Fenton [in press (b)]. Raw steel production in 2000 increased in the United States by about 4%. Globally, the increase was even greater to give a new record for the world (Reynolds, 2001). Because the U.S. economic downturn in 2000 continued into 2001, however, in the immediate future the outlook was for a slump. The October 2000 midterm forecast for 2000 through 2005 of the International Iron and Steel Institute suggested a slow recovery, as the CAGR projected for the North American Free Trade Agreement countries was only 0.9% (Ian Christmas, Secretary General, International Iron and Steel Institute, October 3, 2000, IISI survey reveals renewed world steel consumption growth, accessed June 1, 2001, at URL http://www.worldsteelorg/trends_indicators/demand.html). For the foundry industry, declines in 2001 were foreseen for nearly all iron and steel castings categories. Longer term CAGRs for the 2000 through 2010 period were given as about 2% for iron castings overall and 0.8% for steel castings (Kirgin, 2001). For the world overall, silicon consumption as ferrosilicon during the first decade of the 21st century was not expected to have a CAGR greater than 1.5% to 2% (Roskill Information Services Ltd., 2000, p. 6).

Demand for silicon metal comes mainly from the aluminum and chemical industries. During the two decades leading up to 2000, Western World demand for silicon has had a CAGR of about 4.7%, and the chemicals sector of this demand has had a CAGR of nearly 7% (Linde, 2000). During the past 5 years, Western World silicon consumption has varied by region, having suffered declines in Asia and uneven growth in the United States (Roskill, 2000, p. 4). On the basis of a forecast for the foundry industry, demand for silicon by the aluminum castings industry can be expected to decline marginally in 2001, but to grow reasonably stronger thereafter until 2010 at an annual rate of 3.8% (Kirgin, 2001). This growth may not translate directly into increased demand for silicon because of an increase foreseen in recycling of automotive aluminum scrap. This adds to uncertainty as to whether Western World demand for silicon can continue to experience a CAGR of greater than 4% (Linde, 2000).

SILVER

By Henry E. Hilliard

Domestic survey data and tables were prepared by Mahbood Mahdavi, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

The difference between the high and low prices for silver in 2000 was less than $1.00 per troy ounce. Except for a brief period in February when the high for the year of $5.53 per ounce was reached, the silver price moved steadily downward in 2000 to an average of $5.00 per ounce, 5% lower than the 1999 level. This smaller movement in price occurred at a time when fabrication demand increased by 5% and more than 5,900 metric tons (t) of above ground stocks were needed to meet world demand. Lower demand in the photographic sector was more than offset by increased demand in jewelry and silverware and an 11% increase in industrial applications, where silver used in electrical and electronics were large growth areas.

According to the Silver Institute, world mine output of silver increased for the sixth consecutive year and at 18,900 t was the highest in history; secondary supplies at 5,600 t from old scrap were the second highest level in 20 years. U.S. Government stocks, the only silver used for the various coin and commemorative programs, decreased by 717 t to a level of 678 t in 2000. Stocks located in the principal exchanges increased 17% to 2,920 t in 2000.

Global reserves of silver in demonstrated resources from producing and nonproducing deposits at the end of 2000 were estimated to be 280,000 t by the U.S. Geological Survey (USGS). Reserves for the United States were estimated to be 33,000 t. The reserve base (reserves plus measured and indicated resources that are marginally economic and some of those resources that are currently subeconomic) for the five leading silver producing countries (Australia, Canada, Mexico, Peru, and the United States) were estimated to be about 232,000 t or 55% of the world total.

The USGS has issued a report on undiscovered gold, silver, copper, lead, and zinc deposits in the United States (U.S. Geological Survey, 2000, p. 10). The estimate of the amount of silver in undiscovered mineral deposits ranged from greater than 290,000 t at a 90% probability to greater than 660,000 t at a 10% probability. The mean estimate for silver in undiscovered deposits was 460,000 t. Total discovered silver resources in the United States were estimated to be 330,000 t.

Legislation and Government Programs

The major legislative action affecting silver was the passage of the Commodity Futures Modernization Act of 2000 (CFMA) on December 15. Contrary to the recommendation of the

Silver in the 20th Century

At the beginning of the 20th century, the major uses for silver, other than coinage, were for jewelry and sterlingware. Mexico and the United States were the leading producers. U.S. production averaged about 1,700 metric tons per year. During World War II, technological advances that influenced the outcome of the war were made in electronics and photography. After the war, this technology was used to develop new consumer products. As the demand for consumer goods increased, so did the demand for silver, and as a result, the market price for silver increased. The Silver Act of 1946 authorized the U.S. Treasury to purchase domestically mined silver at $0.905 per troy ounce and to sell its silver holdings at $0.910 per ounce.

In the late 1950s and early 1960s, a second component was added to the demand side of the supply-demand equation—the investor-speculator. Silver certificates, authorized by the Silver Purchase Act of 1934, were redeemable for silver held by the Treasury. At a market price above $1.29, a profit could be made by redeeming the silver certificates, receiving 0.77 ounce of silver from the Treasury, and then selling the silver. In addition, at a market price above $1.38, a profit could be made by melting U.S. circulating coinage for its silver content. Realizing that it could not supply industrial consumers with silver mint coinage and maintain a stock of silver for redemption of silver certificates, the Government began demonetizing silver. Public Law 88-36, which repealed the Silver Purchase Act of 1934 and authorized the printing of Federal Reserve Notes not redeemable in silver, was passed in mid-1963. The coinage act of 1965 eliminated the use of silver in dimes and quarters and reduced the silver content of half-dollars. In 1967, silver coins were withdrawn from circulation and holders of silver certificates were given 1 year to redeem the certificates for silver. With the ending of the relation between silver and the U.S. monetary system in 1968, investor-speculator activities and industrial demand became the determinants of activity in the silver market.

By the turn of the century, silver had lost much of its standing as a precious metal and had become mostly an industrial metal, with about 70% of the metal consumed in industrial applications and photography. Most silver was being recovered as a byproduct of copper, gold, lead, and zinc production. The silver market experienced a period of volatility between 1979 and 1988, with the price reaching a high of $49.45 per ounce in 1980. The price spike, caused by the activities of a few investor-speculators, was short lived. Since then, the price has been mostly stable, averaging around $5.00 per ounce. U.S. mine production of silver in 2000 was about 1,860 tons.

Digitized by Google

President's Working Group on Financial Markets, the Congress exempted metals from the close supervision of the Commodities Futures Trading Commission (CFTC). The CFMA, however, did retain for the CFTC the authority to use its considerable tools to protect the public interest against fraud and price manipulation in the exempted metal commodities. Rules to implement the changes in regulating futures are still being finalized by the CFTC (Silver Users Association, 2001).

The Defense Logistics Agency (DLA) delivered all of the remaining 466,600 kilograms (kg) of silver in the National Defense Stockpile to the U.S. Mint for use in its coinage program. Under an agreement with the U.S. Treasury Department, the metal will continue to be carried as DLA stocks until the metal is consumed by the Mint. The transfer marked the end of the silver stockpile era, which at times was a hotly debated issue between silver users and producers. The stockpile is managed by the Defense National Stockpile Center, a branch of the DLA since the late 1960s. Part of the original 5,132 t of silver in the stockpile was auctioned in 1981, and the remainder has been used in the Mint's American Eagle coinage program. With the silver about to be exhausted, the Washington, DC-based Silver Institute turned bullish on the metal. The Institute concluded that when the Mint depletes its silver reserves, it must purchase silver for its coinage program on the open market and thereby boost silver demand by up to 1%. The Silver Users Association (SUA) disagreed, stating that the metal had been merely moved from one government warehouse to another and that the Mint had been using only about 218 metric tons per year (t/yr). At that rate, it would take about 6 years to use up the remaining Mint silver, which the SUA estimated to be about 1,400 t (Platt's Metals Week, 2000b).

The U.S. Mint is responsible for safeguarding much of the Nation's precious metals and strategic stockpiles and is the custodian of a significant portion of its silver resources. The values of the resources are reported at the lower of cost or market value. Amounts and values of custodial silver in the custody of the Mint at the end of September 30, 2000, were 220,063 kg of silver with a market value of $34.58 million (at $4.8875 per fine troy ounce) and a statutory value of $9.148 million. A statutory rate of $1.29292 per fine troy ounce was used to value the custodial reserves held by the Mint (U.S. Mint, August 14, 2001, United States Mint 2000 annual report, accessed August 16, 2001, via URL http://www.usmint.gov).

Production

In 2000, silver was produced in the United States from precious-metal ores at about 30 lode mines and from base-metal ores at about 24 lode mines. More than 30 t of silver was produced at each of 11 mines; their aggregated production equaled about 80% of total domestic production. Fewer than 10 placer operations recovered silver in 2000, and the quantity recovered was less than 1% of the total domestic production of 1,860 t.

The Sunshine Mine and Refinery Complex.—The Sunshine Mine and Refinery Complex, in the Coeur d'Alene mining district near Kellogg, ID, is comprised of the Sunshine Mine, a 1,000-ton-per-day (t/d) concentrator, an antimony refinery, a silver refinery, and associated facilities. The facility is an integrated operation that can produce refined silver with a purity of 99.99%. The silver refinery has the capacity to recover up to 249 t/yr of silver and 1,810 t/yr of copper.

The Sunshine Mine, one of the few remaining primary silver-producing mines, is an underground mine that began operations in 1884 and has produced more than 10,900 t of silver since that time. The underground workings consist of multiple levels developed of the Jewel shaft, the main production shaft. It extends from the surface to a depth of 122 meters (m) and is complemented by other exterior shafts with developed levels as deep as 170 m. The ore extracted from the Sunshine Mine was processed by the flotation concentrator, which produced a high-grade silver concentrate and a lead concentrate. The silver concentrate was transferred to the antimony refinery for antimony removal. After antimony removal, the silver concentrate was either transferred to the company's silver refinery for recovery of silver and copper or sold to a commercial smelter. Sunshine suspended operations at its silver refinery in 1995 pending higher levels of available feed and began shipping its silver concentrate to an outside smelter (Sunshine Mining & Refining Co., 2001a).

In September 2000, Sunshine Mining & Refining filed for chapter 11, allowing the silver miner to reorganize while receiving protection from its creditors (Metal Bulletin, 2000).

On February 16, 2001, Sunshine Mining & Refining announced that the Sunshine Mine was closed. The closing came shortly after Sunshine was notified by its primary customer that it was closing the smelter to which the Sunshine Mine shipped concentrates and that the smelter would no longer accept deliveries. Prior to the announcement, the mine's management sought alternative economic markets for the mine's production; however, the company was not able to secure an alternate and economically viable contract for its concentrates. The mine was placed on care-and-maintenance, and Sunshine was forced to initiate a mass layoff of its employees. The mine produced 121 t of silver in 2000 (Sunshine Mining & Refining Co., 2001b).

McCoy/Cove Gold-Silver Mine.—Ore and waste rock was mined from the open pits at a rate of 51,000 t/d in 2000 compared with 107,000 t/d in 1999. The lower mining rate was attributed to higher development requirements and to mining less productive drift-and-fill cuts as opposed to mining open stopes in 1999. The mill at McCoy/Cove used flotation and agitation leach circuits to recover gold and silver from high-grade oxide ore and sulfide ores not amenable to heap leaching. The majority of the ore processed through the mill in 2000 was from sulfide ores mined during the year. The Cove South Deep underground mine contributed 54,500 t to the mill and produced approximately 333 kg of gold and 134 t of silver. In 2001, McCoy/Cove will process ore from stockpiles and the Cove South Deep underground mine. Residual heap leaching was expected to continue in 2001. As a result, McCoy/Cove is expected to produce about 60% less gold and silver in 2001 compared with the 5,100 kg of gold and 383 t of silver produced in 2000 (Echo Bay Mines Ltd., 2001).

Lucky Friday Mine.—The Lucky Friday Mine, a deep underground silver and lead mine in northern Idaho and 100%

Digitized by Google

owned by Hecla Mining Co., has been a producing mine since 1958. In 1991, Hecla discovered several mineralized structures containing high-grade silver ores in an area known as the Gold Hunter property about 1,500 m northwest of the then-existing Lucky Friday workings. A feasibility study was completed in 1997, and full production was reached in the second quarter of 1998. The principal mining method at the Lucky Friday Mine was ramp access, cut-and-fill. Ore produced from the mine was processed in a 1,000 t/d conventional flotation mill. The flotation process produced a silver-lead concentrate and a zinc concentrate. In 2000, ore was processed at a rate of 953 t/d at the mine site and produced 156 t of silver; silver production in 1999 was 138 t. During 2000, about 94.0% of the silver, 93.6% of the lead, and 41.4% of the zinc was recovered (Hecla Mining Co., 2001b).

Greens Creek Mine.—The Greens Creek Mine is a joint-venture arrangement of Hecla Mining Co., Kennecott Greens Creek Mining Co. (manager of the mine), and Kennecott Juneau Mining Co. Kennecott Greens Creek and Kennecott Juneau are wholly owned subsidiaries of Kennecott Corp.

Greens Creek, a polymetallic deposit containing gold, lead, silver, and zinc, lies within the Admiralty Island National Monument in Alaska. The Greens Creek property includes 17 patented load claims and one patented millsite claim in addition to property leases from the U.S. Forest Service. In 2000, Greens Creek mined approximately 1,500 t/d underground from the 200 South, the Southwest, and the West ore zones. Ore from the underground trackless mine was milled at the mine site. The mill produced gold/silver doré and bulk lead and zinc concentrates. In 2000, the mine produced 295 t of silver compared with 327 t in 1999 (Hecla Mining Co., 2001a).

Galena Mine.—On September 9, 1999, Coeur d'Alene Mines Corp. acquired 50% of Silver Valley Resources Corp. from ASARCO Inc., increasing its ownership interest in Silver Valley to 100%. Silver Valley owned and operated the Coeur and Galena Mines in the Coeur d'Alene mining district of Idaho. The Galena Mine property is immediately west of the city of Wallace in Shoshone County in northern Idaho. The mine is an underground silver-copper mine and is served by two vertical shafts. The mine uses the drift-and-fill mining method with sand backfill to extract ore from the high-grade silver-copper vein deposits that constitute the majority of the ore reserves. Silver and copper are recovered by a flotation mill that produces a silver-rich concentrate. Silver recovery through the mill averaged 96% in 2000, which was consistent with 1999. In 2000, the mine produced 125 t of silver compared with 70 t in 1999 (Coeur d'Alene Mines Corp., 2001).

Consumption

Silver has become mostly an industrial metal with demand made up almost exclusively of four major components—electrical and electronic, photography, jewelry, and silverware. In 2000, U.S. consumption of silver, including scrap, was estimated to have been about 5,600 t. Photography, the largest end-use category, accounted for about 2,990 t. The second largest end-use category, batteries/electrical/electronic products, consumed about 1,060 t. About 500 t of silver was consumed in sterlingware, jewelry, and silverplate. Global consumption was estimated to have been 25,000 t, an increase of more than 435 t from that consumed in 1999 (Silver Users Association, 2000).

Prices

Unlike the high prices for platinum-group metals, the price of silver was mostly flat in 2000. Silver prices showed some strength in the first few weeks of the year, reaching the high of $5.75 for the year in early February. Despite strong demand, prices began a long descent in late February that lasted through the rest of the year. The average price in 2000 was $5.00 per ounce, $0.25 below the average for 1999.

Trade

In 2000, the United States imported 3,940 t of silver in ash and residues, ores and concentrates, doré, and refined bullion. The value of these imports was $654 million. Canada (31%), Mexico (38%), and Peru (2%) were the leading foreign sources of imports. The United States exported 380 t of silver in ore and concentrates, refined silver bullion, and doré. The value of these exports was $61.7 million.

World Review

Global silver supply increased in 2000 because of strong growth in the mining sector and disinvestment in a market where the price of silver was in decline for most of the year. Much of the increase in silver supply can be attributed to the return of the Mexican silver industry to a more dominant position after lower than normal output in 1999. Restrictions imposed on Industrias Peñoles S.A. de C.V.'s Torreón processing facility were lifted in February and full production was reached by June 2000. Another factor was increased production at the giant Cannington silver-lead-zinc mine in Australia. Cannington was the leading silver producing mine in 2000, and Peñoles retained its position as the leading silver producer. Global production in 2000 increased 7% to 18,900 t compared with 17,700 t in 1999.

China.—China ended its state monopoly of the buying and selling of silver, first on a trial basis from August 1999, and then officially on January 1, 2000. For the first time since 1949, domestic silver producers are no longer required to sell their production to the People's Bank of China (PBOC), previously the sole purchaser and distributor of silver in China. The Government also discontinued the official silver price, set by the PBOC, and the license system for processing and trading silver articles, excluding silver coinage. The Shanghai-based Huatong Nonferrous Metal Trading Center was designated as the first market to operate silver trade in the country as of January 1, 2000. After opening the market, China encouraged silver exports and limited imports. China produces about 1,300 t/yr of silver and consumes about 800 t/yr (Platt's Metals Week, 2000).

Mexico.—Strong world demand for silver encouraged more investment by Mexican silver producers resulting in a production increase of 6% to 2,620 t in 2000. Output in 1999

Digitized by Google

was 2,467 t, substantially lower than the record 2,686 t produced in 1998.

Mexico derives about 50% of its production from primary silver mines and the balance as a byproduct of copper, lead, and zinc production. Mexico's leading silver producer, Peñoles, contributed 1,390 t of mined silver in 2000, more than 50% of the country's total output; refined silver output was a record 2,302 t. Normal operations resumed at the Torreón refinery in 2000, but this was not the only reason for increased production. At Peñoles' Tizapa Mine, output rose by 20% to 212 t, and production at Mina Proaño increased by 84 t to 744 t. The results at Proaño were largely due to expansions completed at the mine in 1999 that raised ore output by about 30% (Silver Institute, 2001, p. 19).

Central America and South America.—In 2000, there was a significant change in the source of silver supply in South America. Output from primary silver mines declined by 42%, while silver as a byproduct from gold and lead-zinc operations increased significantly. The change mostly resulted from the completion of mining at the high-grade Chimberos silver deposit in Chile, which produced 510 t of silver in 1999. With the closure of Chimberos, operators concentrated equipment and personnel on the adjacent La Coipa gold mine, with the result that silver output at the mine increased by more than 50%. Further gains were made at El Peñon gold mine, which contributed 125 t in 2000. According to the Silver Institute, Peru increased its silver output by 9% to 2,438 t, driven by growth in primary gold, copper, and zinc-lead operations. In 2000, Central America's and South America's share of global silver production fell by 2% to 4,500 t, representing about 24% of global production (Silver Institute, 2001, p. 19-20).

Current Research and Technology

Bacteria Resistant to Silver May Have Industrial Applications.—Scientists in Sweden have isolated bacteria that grow silver crystals and store them on the edges of their cell walls. The bacteria, *Pseudomonas stutzeri*, were originally found growing naturally on rocks in silver mines. The researchers were able to grow the bacteria in the laboratory and manipulate the shape in which they formed silver crystals. Most of the crystals were composed of pure silver, but some were silver sulfide. The scientists also discovered that the bacteria could produce and store as much as 25% of the cell's weight in silver. This discovery could lead to new techniques for the recovery of silver from ores, as well as growing superthin and elasticlike silver crystals to specific shapes and sizes for use in electronics and optical applications (Silver News, 2000a).

Government Scientists Produce Silver-Only Dental Fillings.—Metallurgists at the U.S. National Institute of Standards and Technology (NIST) have developed a method for making pure silver powder for use in filling dental cavities. Traditionally, an amalgam of mercury, which has strong corrosion resistance and good mechanical strength, was the material of choice. Now, NIST scientists have found a way to remove naturally occurring silver oxide from the surface of silver metal powder by treating it with a dilute acid solution that removes the oxide layer. The pure silver particles can then be compacted with normal dental tools until they harden. These fillings are 80% as dense and at least as strong as mercury-alloy amalgams. The observed values of flexural strength for the silver compacts were reported to be equal or superior to mercury amalgams. Corrosion resistance, microleakage, and marginal toughness values of the compacts were found to be superior to those of amalgams. Although the American Dental Association has deemed mercury-containing amalgams safe, as long as the materials remain intact, materials that do not contain mercury are more desirable (Advanced Materials & Processes, 2000).

Spent Silver Catalyst May be Used as a Bactericide.—Catalysts make industrial processes, such as the production of plastics, more efficient by increasing the rates of reaction and eliminating unwanted chemical reactions and their byproducts. After periods of use, catalysts become deactivated and must be regenerated. In the case of silver catalysts, refiners remove the silver from its substrate, usually alumina, refine it, and place it onto a new substrate. Although not all of the silver can be economically removed from the substrate, studies have shown that the used silver catalyst substrates retain enough silver to enable the material to be used as an effective bactericide or fungicide. When immersed in water, the spent catalyst will release the more readily available silver immediately, inactivating a large range of bacteria, including *E. coli.* The remaining silver, more strongly bound within the pore structure of the alumina, dissolves more slowly and supplies a concentration of about 5 parts per billion and provides a long-term sanitation effect (Silver News, 2000b).

Outlook

Mine production of silver in 2000, as in the previous 11 years, was less than demand. The difference between demand and newly mined silver was filled by aboveground stocks. In the past 11 years, referred to by some as the "deficit" years, the holders of aboveground stocks have released almost 50,000 t of silver at an average price of $4.86 per ounce, or about $0.14 below the average in 2000. The scale of the deficit was slightly smaller than in 1999 as stockholders' disinvestment of silver (estimated by the Silver Institute at 1,300 t) provided 4.8% of the world's fabrication demand.

The outlook for the silver market depends somewhat on the level of future prices needed to continue filling the gap between demand and newly mined and secondary silver. It has been shown that disinvestment continues at every price level—even when approaching a 20-year low of $3.55 per ounce in 1993. Disinvestment, therefore, is expected to continue to fill the longstanding deficits in the supply of silver. While the market takes these deficits in stride, thanks to the continued release of stocks, lower prices are resulting in some mine closures. If low prices persist or fall even more, it could induce further high-profile mine closures and the suspension or delay of new projects. The size of the currently forecasted deficits could escalate further, which would result in even speedier drawdown of stocks.

SLAG—IRON AND STEEL

By Rustu S. Kalyoncu

Domestic survey data and tables were prepared by Robin C. Kaiser, statistical assistant.

As early as 350 B.C., the Greek philosopher-physician Aristotle prescribed iron slags for healing wounds. In the ensuing centuries, a number of applications for iron and steel slags were found. However, it was not until the early 20th century, when the modern processes of iron and steel production were developed, that the commercial, large-scale use of iron and steel slags became economical.

The American Society of Testing and Materials (ASTM) (1999) defines blast furnace slag as "the non-metallic product consisting essentially of calcium silicates and other bases that is developed in a molten condition simultaneously with iron in a blast furnace." To the casual observer, one of the most striking features of an iron and steel plant is the site of a mountainous slag pile that presents a continuous display as ladle after ladle pours its incandescent load down the side in the endless accumulation of this waste product. Almost a century ago, the term waste product aptly described slag. Slag was considered to be essential in the production of iron, but once it served its purpose in refining the metal, it was strictly a nuisance with little or no use. The usefulness of slags was realized with the first ore smelting process. The use of slags became a common practice in Europe at the turn of the 19th century, where the incentive to make all possible use of industrial byproducts was strong and storage space for byproducts was lacking. Shortly after, many markets for slags opened in Europe, the United States, and elsewhere in the world.

In the production of iron, the blast furnace (BF) is charged with iron ore, fluxing agents (usually limestone and dolomite) and coke as fuel and the reducing agent. The iron ore is a mixture of iron oxides, silica, and alumina. From this and the added fluxing agents, alkaline earth carbonates, molten slag, and iron are formed. Oxygen in the preheated air blown into the furnace combines with the carbon of the coke to produce the needed heat and carbon monoxide. At the same time, the iron ore is reduced to iron, mainly through the reaction of the carbon monoxide with the iron oxide to yield carbon dioxide (CO_2) and metallic iron. The fluxing agents dissociate into calcium and magnesium oxides and carbon dioxide. The oxides of calcium and magnesium combine with silica and alumina to form slag. The slag is transported into a cooling pit either directly or via iron ladles, depending on the distance between the pit and the furnace.

The principal constituents of iron and steel slags are silica (SiO_2), alumina (Al_2O_3), calcia (CaO), and magnesia (MgO), which make up 95% of the composition. Minor elements include manganese, iron, and sulfur compounds, as well as trace amounts of several others. The physical characteristics, such as density, porosity, and particle size, are affected by the cooling rates of the slag and its chemical composition. Depending on the cooling method, three types of BF slag are produced: air-cooled, expanded, and granulated.

Allowing the molten slag to cool slowly in air in an open pit produces air-cooled slag. Air-cooled blast furnace slag is defined in ASTM standard C-125 (American Society for Testing and Materials, 1999) as "the material resulting from solidification of molten blast furnace slag under atmospheric conditions. Subsequent cooling may be accelerated by application of water to the solidified surface." The solidified slag has a vesicular structure with closed pores. The rough vesicular texture of slag gives it a greater surface area than smoother aggregates of equal volume and provides an excellent bond with portland cement, as well as high stability in asphalt

Slag—Iron and Steel in the 20th Century

Early use of blast furnace slag in the United States was prompted by the desire to make use of material that was considered an expensive waste product. Its use in earnest started in the early 1900s in the construction field, principally for railroad ballast, portland-cement-concrete aggregate, and aggregates for bituminous and other types of road construction. The National Slag Association carried out a survey of slag shipments in the United States for the first time in 1938. In 1939, the first year for which comprehensive figures of marketed slag are available, 8.3 million metric tons of blast furnace slag valued at $6.4 million was used. The slag output from blast furnaces in 1947, the first year in which the U.S. Bureau of Mines collected production statistics, reached almost 30 million tons. Most slag was used in highway construction and railroad ballast.

In 2000, 8.9 million tons of blast furnace slag valued at $58.3 million and 5.1 million tons of steel slag valued at $20.1 million were used. Major uses were in road construction, asphaltic concrete aggregate, portland cement manufacture, and various concrete products. In the early years of slag use, prospective consumers thought that slag was subject to disintegration and corrosion and was brittle. Slag cements also were questioned, and slag wool was believed to have high sulfur content. Only after years of research and promotion were these objections overcome. In 2000, the ferrous slag industry enjoyed the benefits of many individual and collective efforts expended in the development of slag markets. A broader market existed for slag, from mineral wool to roofing granules to agriculture. Virtually all of the slag produced by the iron and steel industry throughout the world was used in such applications as asphaltic concrete aggregate, cement extenders, fill, railroad ballast, road bases, and roofing granules.

Digitized by Google

mixtures.

Expanded slag is formed through controlled rapid cooling of molten slag in water or in water with combination of steam and compressed air. Steam and other gases enhance the porosity and vesicular nature of the slag, resulting in a lightweight aggregate suitable for use in concrete. Quenching the molten slag into glass granules by using high-pressure water jets produces granulated slag. Quenching prevents the crystallization of minerals constituting the slag composition, thus resulting in a granular, glassy aggregate. This slag is crushed, pulverized, and screened for use in various applications, particularly in cement production, because of its pozzolanic (hydraulic cementitious) characteristics.

Slags are also coproducts of steelmaking processes. Production of steel calls for the removal of excess silicon by mineralization and of carbon by oxidation from pig or crude iron. Steel slag is a hard, dense material somewhat similar to air-cooled iron slag. It contains significant amounts of free iron, giving it its high density and hardness, which make it particularly suitable as a road construction aggregate.

Slag is transported to processing plants, where it undergoes crushing, grinding, and screening operations to meet various use specifications. Processed slag is either shipped to its buyer for immediate use or, in slack seasons, stored.

Legislation and Government Programs

Classification of slags under several standard waste categories has been the subject of a number of past Government initiatives. The National Slag Association reported no major Government action concerning slag in 2000 (R.Y. Twitmyer, President, National Slag Association, oral commun., 2000). The effect of increased spending on highway construction and repairs, as a result of the passage of the Transportation Equity Act for the 21st century (Public Law 105-178) by Congress in 1998, with its $205 billion spending plan, did not show on the consumption and price of slags in 2000.

The Portland Cement Association is promoting slag use in portland cement production. The potential for a carbon tax levy on CO_2 emissions may provide the cement producers with incentives to find ways of reducing CO_2 emissions in portland cement production, where the burning fuel and decomposition of carbonates in the raw feed contribute to CO_2 emissions.

Texas Industries has developed a process for cement clinker production involving the use of steel slag. In this process, called CemStar, steel slag is fed into the rotary kiln as a part of the raw meal. Replacing a part of the raw meal directly with slag will result in the lowering of CO_2 emissions directly proportional to the quantities of slag used. Additional refinements of the process have been reported (Robert D. Rogers, President, Texas Industries, oral commun., 2000).

Production

The iron and steel industry does not routinely measure slag output; therefore, actual annual ferrous slag production data in the United States do not exist. The data collected by the U.S. Geological Survey (USGS) reflect the slag processing industry's sales rather than the output. Slag outputs in iron and steel production are highly variable and depend, partly, on the composition of the raw materials and the type of furnace. Typically, for ore feed with 60% to 65% iron, blast furnace slag production ranges from about 220 to 370 kilograms per metric ton of pig iron produced. Lower grade ores yield much higher slag fractions, sometimes as high as 1 ton of slag per ton of pig iron. Steel slag outputs are approximately 20% by mass of the steel output. About one-half of the slag is entrained steel, which is generally recovered and returned to the furnace. After removal of the entrained steel, the marketable slag is equivalent to about 10% to 15% of the original steel output.

According to statistics reported by the American Iron and Steel Institute, U.S. pig iron production was about 46 million tons (Mt) and 48 Mt in 1999 and 2000, respectively. The iron slag production figures for these years were about 11.5 Mt and 12 Mt in 1999 and 2000, respectively. Similarly, U.S. steel production was reported to be 97 Mt for 1999 and 101 Mt for 2000. The expected steel slag production was about 11 Mt for 1999 and 13 Mt in 2000. As with the United States, no data are available on world slag production. The International Iron and Steel Institute (2000, p. MM16) reported the world pig iron output to be about 570 Mt and crude steel production to be 828 Mt in 2000. The estimated figures for ferrous slag production from this output was approximately 200 Mt.

Tables 1 through 8 list data compiled from the USGS survey of domestic slag processors. The data for 1999 and 2000 reflect a response by 90% of the processors queried. Where applicable, estimates have been incorporated for data omitted from the returned questionnaires. Table 8 lists the production facilities that responded to the survey in 2000. Redland Mill Services no longer appears in the table because Lafarge Corp. bought it 2 years ago.

Nucor Corporation's new 1-million-ton-per-year electric-arc furnace steel mill in Hertford County, NC, the construction of which was started in 1998 (Kalyoncu, 1999), became operational in October 2000 (Giff Daughtridge, plant manager, Nucor Plant, oral commun., 2001). Currently [2000], the mill is operating at 70% capacity and generating approximately 25,000 tons of slag, which is processed by Heckett MultiServ Co.

GSC Partners is in the process of acquiring Envirosource (R.Y. Twitmyer, National Slag Association, oral commun., 2001).

Consumption

Uses of iron and steel slags range from building and road construction to waste stabilization. Iron and steel slags are also used in cement manufacture, concrete aggregates, agricultural fill, glass manufacture, and as a mineral supplement and liming agent in soil amendment. The correlation between slag production and availability is not a good indicator of consumption trends because time lags between production and sale of the slag to the final customer can be significant. The primary reason for the lag is the necessity of aging the new slag to reduce its free-lime content for certain applications, such as concrete production. High levels of free lime can adversely affect concrete performance. Generally, slag, especially steel slag, will be stored to cure for 6 months or longer to allow expansion of dicalcium silicate and to reduce the free-lime content to acceptable levels. Furthermore, many slag producers accumulate large stockpiles to be able to participate in bids to supply large construction projects.

Air-cooled slag accounted for the bulk of slag production (sales) in the United States. The total U.S. sales of about 9 Mt, worth more than $59 million, of domestically produced air-cooled blast furnace slag recorded a slight increase in value (table 1). Expanded and granulated slag sales increased. Total revenues of more than $141 million (iron plus steel slags) for

Digitized by Google

2000 were slightly higher than those of 1999. The mid-Atlantic region, for a second year, remained the leader in sales value of blast furnace slag with $55 million, accounting for more than 45% of total revenues for the whole country, with the north-central region accounting for most of the remaining business (table 3).

In 2000, sales for concrete and asphaltic road construction, including road base, again accounted for more than three quarters of the consumption of air-cooled BF slags in the United States; other uses were in soil conditioning, sewage treatment, and mineral wool production (table 4).

Road base was the primary use of steel slag, followed by fill and asphaltic concrete aggregates. The steel slag sales of $20.1 million in 2000 lagged behind the 1999 figure of $23 million by almost 13% (table 5). Slag prices showed a range of values depending on their use categories (table 6). A significant amount of slag, 2.4 Mt, was never shipped but used at the plants (table 7).

In 2000, the United States imported 1.5 Mt of ferrous slags. Granulated blast furnace slag (GGBFS), which commands the highest price among ferrous slags, led the imports. In 2000, approximately 1 Mt of GGBFS was imported. Imports of GGBFS, in descending order, were mainly from Italy, Canada, France, South Africa, and Brazil. Principal discharge ports were Tampa, FL, New Orleans, LA, Philadelphia, PA, and Detroit, MI. In 2000, imports accounted for about 5% of total ferrous slag shipments in the United States.

Transportation

Most of the of ferrous slag sold and not consumed at the plant was transported by truck; rail and barge transportation accounted for 21.5% of the total (table 7). Most ferrous slag was transported less than 100 kilometers; trucks were the most economical means of transportation for such distances.

Current Research and Technology

No significant developments were made in slag processing technology during 2000. Because slag is a low unit-value, high-volume commodity, and slag processing is an established, conservative industry, all the slag that is processed is readily sold. Therefore, the industry seldom feels the need for innovations and, therefore, invests little, if any, in expensive research efforts. Previously reported advancements in granulating techniques (Kalyoncu, 1999) resulted in some improvements in slag granulation systems, especially in reducing the energy costs.

Outlook

Potential classification by the U.S. Environmental Protection Agency of iron and steel slags as hazardous wastes is of constant concern to the slag industry. Absent such a classification, ferrous slag has a secure future in the construction industry. Some blast furnace operations, however, have been closing because of an inability to compete in the marketplace. In the case of continuing plant closings, availability of domestic blast furnace slag may decline, which may necessitate an increase in imports. With its more limited uses, the long-term supply of steel slag appears to be more stable. An increase in the use of steel slags may be on the horizon as blast furnace slag production declines.

SODA ASH

By Dennis S. Kostick

Domestic survey data and tables were prepared by Jeff Milanovich, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Soda ash, also known as sodium carbonate (Na_2CO_3), is an alkali chemical refined from the mineral trona or naturally occurring sodium carbonate-bearing brines (both referred to as natural soda ash), the mineral nahcolite (referred to as natural sodium bicarbonate, from which soda ash can be produced), or manufactured from one of several chemical processes (referred to as synthetic soda ash).

Production

Soda ash production and inventory data were collected by the U.S. Geological Survey (USGS) from monthly, quarterly, and annual voluntary surveys of the U.S. soda ash industry. A survey request was sent to each of the six soda ash companies, all of which responded, representing 100% of the total production data in this report (table 1). The information and data are fundamental resources for analysis, both within and outside the government. The soda ash data and information are used by the public and private sectors to better understand minerals and materials usage and the ultimate disposition of materials in the economy and in the environment and to develop public and private sector policies and practices that better utilize our mineral and material resources. Some of the organizations that use the soda ash data and information are financial institutions, State and Federal agencies, soda-ash-consuming industries (e.g., glass, chemicals, and detergents), educational institutions, and the general public.

U.S. production of natural soda ash from California, Colorado, and Wyoming in 2000 was 10.2 million metric tons (Mt), which was virtually the same as that of 1999. Based on about 14.5 Mt (16 million short tons) of total nameplate capacity, the U.S. soda ash industry operated at 70% of total capacity. This capacity utilization rate appears low because it includes the full nameplate capacity of 900,000 metric tons (t) (1 million short tons) for American Soda, L.L.P., which began late in the year with minimal output but was included in the industry total because nameplate capacity is based on the industry total as of December 31 of each year. Furthermore, the capacity utilization rate was low because OCI Chemical Corp. and FMC Wyoming Corp. had idled about 820,000 t (900,000

Soda Ash in the 20th Century

The 20th century has been called the greatest century of industrial progress in the history of civilization. In that time, the world soda ash industry had emerged as an important component of the family of chlor-alkali producers. During the past 100 years, the world soda ash industry expanded rapidly to provide a multitude of new products for millions of users. As the century closed and the new millennium began, the world soda ash industry was undergoing a restructuring as competition increased from new sources and traditional end-use markets changed. The first natural soda domestic soda ash production increased to about 370,000 tons, of which only about 25,000 tons was natural soda ash. In 1900, the majority of U.S. soda ash production was synthetic soda ash produced by four companies operating a total of five plants at Detroit and Wyandotte, MI; Syracuse, NY; Barberton, OH; and Saltville, VA. Natural soda ash was produced from alkaline lakes by five companies operating a total of five plants in Keeler, CA (Owens Lake); Ragtown, NV (Big Soda Lake and Little Soda Lake); Schurz, NV (Double Springs Marsh); and Laramie, WY (Union Pacific Lakes).

Around the beginning of the 20th century, the estimated distribution of soda ash by end use was glass, 25%; sodium bicarbonate and sal soda, 25%; paper manufacture, 20%; soap and chemicals, 20%; and miscellaneous, 10%. Soda ash exports during this period were negligible. As the U.S. population continued to grow after 1900 and the demand for consumer products increased, soda ash production and consumption also increased.

By 2000, soda ash had already become a mature commodity with a growth rate that followed population growth and gross domestic product trends. The United States had become the world leader in production and trade. Soda ash production in 2000 was exclusively from natural sources; the last synthetic soda ash plant in the United States had closed in 1986. Ironically, this last plant was also the first one built in the country in 1884. The rising cost of energy, issues pertaining to pollution, and competition from natural soda ash were the factors that forced the closure of all the U.S. synthetic soda ash plants and many of the synthetic plants in the world leading up to 2000. The U.S. soda ash industry in 2000 consisted of six producers that mined sodium-carbonate-bearing deposits in California, Colorado, and Wyoming.

Glass was still the largest end use for soda ash in 2000, representing 50% of total domestic consumption. Soda ash was still used for soap and detergents and chemicals, as it was a century before; new uses such as flue gas desulfurization and water treatment also developed. The Belgian company Solvay S.A., which invented the Solvay synthetic soda ash production process and introduced it to the United States in 1884, competed with U.S. producers for most of the 20th century only to become a partner in the last decade and an important member of the U.S. soda ash industry in 2000.

Digitized by Google

short tons) and 590,000 t (650,000 short tons), respectively, of available capacity until market conditions improved.

At the beginning of 2000, the U.S. soda ash industry consisted of five companies: four in Wyoming operating five plants that produced soda ash from underground trona ore and one in California that produced soda ash from sodium-carbonate-rich brines. A sixth company came on-stream in October that produced soda ash and sodium bicarbonate from underground nahcolite in Colorado. Nahcolite is a mineral that is naturally-occurring sodium bicarbonate (its name is derived from the chemical elements contained in sodium bicarbonate: Na (sodium), H (hydrogen), C (carbon), O (oxygen), and "lite" (stone).

Increasingly, foreign synthetic soda ash producers and consumers had become involved in the U.S. natural soda ash industry. In 2000, foreign investment in U.S. soda ash operations was 36% of total nameplate capacity. The six U.S. companies have partners from Belgium, Japan, and the Republic of Korea (table 2).

In October 2000, the newest U.S. soda ash facility began solution mining at an underground nahcolite deposit in the Piceance Creek Basin of Rio Blanco County in northwest Colorado. The company, American Soda, L.L.P., was formed in 1996 as a joint-venture partnership with Williams Soda Products Co., which was a wholly-owned subsidiary of The Williams Companies, Inc. (60%), and American Alkali, Inc. (40%). The water-soluble nahcolite was associated with oil shale on Federal sodium mineral leases. Hot water was injected into wells drilled to a depth of approximately 670 meters (m). A vertical cavern about 150 m to 180 m long was developed and topped with a cap of nitrogen gas to prevent further dissolution and spalling of the cavern roof. A sodium-bicarbonate-bearing solution was recovered and processed to remove the carbon dioxide gas, and the remaining sodium-carbonate-rich solution was pipelined 71 kilometers to the soda ash refinery at Parachute. On November 3, the first soda ash was produced at the plant. Although a small quantity of product was made for test purposes during the remainder of the year, the first commercial deliveries were not scheduled until January 2001. During its first year of production, the plant was scheduled to operate at a rate of about 545,000 metric tons per year (t/yr), but when fully operable, the facility will have a nameplate capacity of 900,000 t/yr of soda ash and about 135,000 t/yr of sodium bicarbonate.

Consumption

The USGS collects reported consumption data by end use on a quarterly basis from the marketing and sales departments of each company. Every effort has been made to categorize company sales within the correct end-use sector. Quarterly reports are often revised in subsequent quarters because of customer reclassifications or other factors. Because all U.S. soda ash companies responded to the quarterly survey, the data represented 100% of the total reported consumption data found in this report.

In 2000, U.S. apparent consumption of soda ash was 6.43 Mt; reported consumption, however, was 6.39 Mt (table 3). Reported consumption and apparent consumption data do not necessarily correspond because reported consumption data were based on actual sales, whereas apparent consumption data were the calculated quantity available for domestic consumption based on balancing supply (production, imports, and inventory adjustments) with external demand (exports).

In 2000, U.S. apparent consumption and reported consumption varied by 40,000 t, which was slightly less than 1% of apparent consumption. The discrepancy between the two forms of consumption was attributed to disagreement between the sources of export data used to derive consumption statistics. The two sources were the U.S. Census Bureau, which reports exports upon departure from U.S. ports, and the soda ash producers, which consider a shipment as exported when their export association, the American Natural Soda Ash Corp. (ANSAC), takes consignment of the product at the California, Colorado, or Wyoming plant sites. Transit times between the plant and port, which can take about 2 to 3 weeks before the cargo is actually exported, and carryover export inventories contribute to the discrepancy between reported and apparent consumption as well.

The distribution of soda ash by end use in 2000 was glass, 50%; chemicals, 27%; soap and detergents, 11%; distributors, 6%; flue gas desulfurization and pulp and paper, 2% each; and water treatment and other, 1% each.

Glass.—Glass manufacture represented about 50% of domestic soda ash consumption: the container sector accounted for 48%; flat, 36%; and specialty and fiber, 8% each. There were 57 glass container manufacturing plants in 24 States that produced a variety of different colored glass containers for various products. About 58% of the container market was clear (flint) glass; 35% was brown (amber) glass; 6% was green, and 1% was miscellaneous colors. The containers are made for beverages (beer, carbonated, and noncarbonated drinks), chemical and household products, food, liquor, medical products, and toiletries and cosmetics.

According to U.S. Census Bureau data, production of glass containers decreased by 3% to 8.56 Mt in 2000 from 8.85 Mt in 1999 primarily because of the beverage sector whose use of glass continued to decline because more soft drinks were packaged in plastic containers than in glass bottles. Production of glass containers for the beer industry increased by 1.9% to 4.04 Mt from 3.97 Mt in 1999. From 1980 to 2000, the output of glass beer containers varied between a low of 2.6 million metric tons per year (Mt/yr) to a high of 4.0 Mt/yr; however, the beer container sector composed 30% of the total quantity of glass containers manufactured in 1980, whereas it accounted for 52% of the sector in 2000. This increase is attributed to the decline in such other sectors as glass food containers [narrow neck (30)%, and wide mouth (26%)] during that time period, with glass food container production decreasing to 2.0 Mt in 2000 from 3.6 Mt in 1980. Production of beverage containers also declined; however, a large amount of data had been withheld since 1996, which made it difficult to accurately determine how much of a decrease there has been since 1980, when beverage containers accounted for 19% of all glass containers.

Although the domestic glass recycling rate was not published for 1999 or 2000, it is assumed the recycling rate remained the same as that of 1998, which was 35%. Of that, 24% was

Digitized by Google

estimated to be post-consumer cullet and the remainder being in-house scrap. Some municipalities had started terminating their glass-collection programs because the price of clean, sorted cullet had declined, thereby making it less attractive to recyclers. Another reason was that breakage during collection had affected the quality of material sold to glass container manufacturers.

In March 2000, Miller Brewing Co. and Continental PET Technologies announced they developed a new plastic bottle for beer for widespread distribution. The bottle had been test-marketed since October 1998 in six major cities, and consumer acceptance was favorable. The benefits of the new container were that it kept the beer colder than aluminum cans and as long as glass bottles, was one-seventh the weight of comparable glass containers, was unbreakable, and was recyclable with other polyethylene terephthalae (PET) containers. The PET beer bottle was accepted in areas where glass bottles were not allowed or were as convenient, such as stadiums, pools, concerts, and beaches (Miller Brewing Co., 2000).

In July, a new PET resin was introduced for beer and other hot-fill applications by KoSa. KoSa was formed in December 1998 when Koch Industries, Inc. (through its subsidiaries Koch International Equity Investments B.V. and Koch Equity Investments, Inc.), and IMASAB S.A. de C.V. purchased the polyester business of Hoechst Aktiengesellschaft. The new plastic beer container provides a lightweight, thermally stable bottle that allows the beer to be pasteurized in the bottle, which up to this time could only be done with glass bottles. The PET bottle also can be used for carbonated soft drinks, water, juice, food, and custom container applications (KoSa, 2000).

Chemicals.—Soda ash is used to manufacture many sodium-base inorganic chemicals, including sodium bicarbonate, sodium chromates, sodium phosphates, and sodium silicates.

According to data from the U.S. Census Bureau, production of sodium bicarbonate decreased by 4% to 486,000 t in 2000 from 505,000 t in 1999 (U.S. Census Bureau, 2000).

In addition to American Soda, which began producing soda ash and sodium bicarbonate from Colorado nahcolite, AmerAlia, Inc., received approval of its environmental assessment from the Bureau of Land Management to proceed with the planned construction of a 68,000 t/yr (75,000-short-ton-per-year) sodium bicarbonate plant in Colorado. AmerAlia's partner, U.S. Filter, Inc., drilled three of the five groundwater monitoring wells around the mine site that will detect any excursion of sodium-bicarbonate-bearing solutions from the solution mined caverns. U.S. Filter was financing 80% of the $40 million project with AmerAlia securing the remaining 20% financing. Startup was scheduled for sometime in 2001 (Industrial Minerals, 2000a).

Soaps and Detergents.—Detergents were the third largest use of soda ash. Soda ash was used as a builder to emulsify oil stains, to reduce the redeposition of dirt during washing and rinsing, to provide alkalinity for cleaning, and to soften laundry water. In addition, soda ash was a component of sodium tripolyphosphate (STPP), another major builder in detergent formulations. Soda ash consumption has been decreasing because phosphatic detergents can contribute to eutrophication, which is an environmental concern. Many regions of the Nation adopted phosphate limitations or bans, affecting about 40% of the U.S. population. A strong U.S. economy boosted demand for industrial and institutional cleaners and automatic dishwashing detergents in the past couple of years. New technology incorporating enzymes in dishwashing detergents and a move toward liquid cleansers, however, may adversely affect STPP consumption in the future.

In response to the environmental concern that cardboard detergent packaging contributes to the volume of landfill waste, detergent manufacturers changed formulations to make compact and superconcentrated products. These reformulations required sodium silicates and synthetic zeolites, which are made from soda ash. Liquid detergents, which do not contain any soda ash, competed with powdered detergents and commanded about 50% of the household laundry detergent market in 2000 compared with 15% in 1978.

Stocks

Yearend 2000 stocks of dense soda ash in domestic plant silos, warehouses, terminals, and on teamtracks amounted to 245,000 t. Producers indicated that a potential supply problem could exist if inventories fell below 180,000 t. Most consumers of soda ash did not have the storage facilities to accommodate large quantities of soda ash and had to rely on suppliers to provide the material on a timely basis.

Prices

In the domestic market, large-volume buyers of soda ash were primarily the major glass container manufacturers whose purchases were seasonal (more beverage containers made in the second and third quarters for summertime beverage consumption). Soda ash sales to the flat glass sector were usually dependent on the state of the economy because the largest use of flat glass was in automobile manufacture and in residential housing and commercial building construction. These two major industrial sectors were especially sensitive to changing economic conditions, and soda ash sales follow trends in the two sectors.

The average annual value for bulk, dense natural soda ash, free-on-board (f.o.b.) Green River, WY, and Searles Valley, CA, was $73.00 per metric ton ($66.23 per short ton), which was a 4% decrease compared with that of 1999. No value data were collected from the Colorado producer because the majority of its yearend output was for test purposes and not for commercial customers. The value is not a price but rather the value of the combined revenue of California and Wyoming bulk, dense soda ash sold on an f.o.b. plant basis at list, spot, or discount prices, on long-term contracts, and for export, divided by the quantity of soda ash sold. The list prices quoted in trade journals or by producers differed from the annual average values reported to and by the USGS. This value may or may not correspond to the posted list prices. The list price for Wyoming bulk, dense soda ash has not changed since it was raised effective July 1, 1995, or as contracts permit, to $105 per short ton from $98 per ton. The California price for the comparable product also increased by $7 per short ton, to $130 per ton from $123 per ton (table 4).

FMC announced a soda ash price increase of $5 per short ton

Digitized by Google

on August 31, effective October 1 or as contracts permit. The company stated that the increase was necessary in order to bring prices to reinvestment levels and to offset rising energy costs. Despite an oversupply of soda ash in the market, FMC forecasted export sales would increase and certain caustic soda customers would switch to soda ash so long as caustic soda prices were high (Chemical Week, 2000a). One week later, OCI Chemical and Solvay Minerals Inc. followed FMC and announced a $5 per short ton price increase (Chemical Week, 2000c). General Chemical Corp. was the next to follow, on September 27, with its $5 price increase (Chemical Week, 2000d); IMC Chemical Co. announced in early October that it would raise its soda ash prices by $5 effective immediately or as contracts permit (Chemical Week, 2000b). The industry indicated that the price increase attempt was in response to an improving supply-demand balance for soda ash during the fourth quarter of 1999. General Chemical issued another $5 per short ton price increase effective December 1 that was followed by FMC, which also raised its price by another $5 per short ton on all grades of soda ash including bulk, bagged, and all material sold through distribution centers, warehouses, and transloaders (Chemical Market Reporter, 2000b). Although there was some success in raising prices in the spot market, the full effect of the increase attempt would not be noticeable until 2001, because 90% of domestic sales were on annual contracts renewable each January.

Foreign Trade

Exports of 3.90 Mt represent about 38% of U.S. soda ash production. The problems in the Asian economies that began in late 1997 continued through 1999 and into 2000. An upturn in the economies in most of the nations, however, was evident by mid-2000, and U.S. soda ash exports began to increase. In 2000, Asia received 44% of the U.S. soda ash exported, accounting for 17% of total domestic output, compared with 38% of total U.S. soda ash exported in 1999 representing 14% of domestic production. The economic problems lasted longer than most market analysts had forecasted, resulting in delays in several domestic soda ash capacity expansions. In 2000, China increased its soda ash production by 9% compared with that of 1999, to 8.34 Mt from 7.65 Mt. Increases in Chinese soda ash production, industry rationalization, and improving economic conditions in Asia may affect the U.S. soda ash export market (Chemical Market Reporter, 2000c).

The U.S. soda ash industry exported the majority of its soda ash through its export association, ANSAC. Because of rising energy and transportation costs, ANSAC raised its selling price by $10 per metric ton, effective November 1 (Chemical Market Reporter, 2000a).

After 2 years of declining export sales, U.S. soda ash exports in 2000 were 3.90 Mt, which was 8% greater than that of 1999. In 2000, U.S. exports to 47 countries, on a regional basis, were as follows: Asia, 44%; North America and South America, 21% each; Europe and the Middle East, 4% each; Africa and Oceania, 2% each; and Central America, 1% (table 6). Shipments to the Caribbean were negligible. The average free-alongside-ship value was $122.52 per ton in 2000 compared with $123.48 per ton in 1999. Although the data in tables 1 and 6 are rounded to three significant digits, the unit values shown are based on the actual unrounded statistics and not the rounded data. The top 10 countries, representing 72% of total U.S. soda ash exports, in decreasing order and percent of total, were: Mexico, 16%; the Republic of Korea, 10%; Japan, 9%; Brazil, 7%; Indonesia, 6%; Taiwan, 5%; Venezuela, 5%; Chile, 4%; and Thailand, 4%. About 57% of all U.S. soda ash exports went through the Columbia-Snake River customs district; the Laredo, TX, customs district was the second largest, with 15% of the total (table 5).

Imports of soda ash decreased by 18% to 75,000 t. The majority (99%) came from Canada, where General Chemical operated a synthetic soda ash plant in Amherstburg, Ontario. The remainder was imported from Bulgaria, Hong Kong, Italy, Japan, Mexico, Turkey, and the United Kingdom. The average customs-insurance-freight value of imported soda ash was $114.32 per ton.

World Review

The largest consumers of soda ash were, for the most part, developed nations; these countries, however, also usually have lower growth rates compared with developing countries, which usually have greater demands for consumer products. Although the production and consumption quantities varied among the countries, the end-use patterns were basically the same; glass, chemicals, and detergents were the major sectors (table 8).

Nine countries had the capacity to produce more than 1 Mt/yr. They are, in descending order, the United States, China, Russia, India, Germany, France, Italy, Poland, and the United Kingdom. Bulgaria, Romania, and Ukraine had production installations that were rated at about 1 Mt/yr; adverse economic conditions, however, had caused these nations to produce below their design capacities. Recent acquisitions or joint ventures with major European soda ash producers that have soda ash manufacturing expertise should reverse this situation in the next few years. Most of these soda-ash-producing countries have large populations that require consumer products made with soda ash. The less developed nations tend to have higher soda ash demands and higher growth rates as soda-ash-consuming industries are developed. In 2000, world soda ash production was estimated to be 34.2 Mt, which was a 3% increase compared with that of 1999.

Canada.—Overcapacity, high energy costs, and low profitability were cited as reasons why General Chemical announced it would close its synthetic soda ash plant in Amherstburg, Ontario, in April 2001 and would reopen the plant when market conditions improved. The plant, which was built in 1919, had a nameplate capacity of 500,000 t/yr (Chemical and Engineering News, 2000).

Germany.—IMC Chemicals closed its synthetic soda ash plant in Duisburg in January 2000. The plant was formerly owned by Matthes & Weber GmbH and had a capacity of 280,000 t/yr, which was about 5% of the European soda ash industry capacity (Industrial Minerals, 2000d).

India.—ANSAC filed a petition with the U.S. Trade Representative to suspend the Generalized System of Preferences for India until there was progress toward fair and equitable access to Indian soda ash markets. The import tariff

Digitized by Google

on soda ash was 38.5%, which was the highest in the world, and other import fees brought the total to 69.9%. Reports indicated that the tariffs would have to be reduced to 12% before U.S. soda ash could be competitive, bringing the net effective import fee to 38.92%, which would include the 12% tariff, a 10% surcharge, an 18% countervailing duty tax, and special import fees (North American Mineral News, 2000).

Japan.—Asahi Glass Co., Ltd., announced it planned to permanently close its synthetic soda ash plant in Kitakyushu by the end of the first quarter of 2001. The decision to close the plant was based on the large capital expenditure required to modernize the facility and the company's investment in the U.S. soda ash industry. Through its subsidiary AG Soda Corp., Asahi has a 20% partnership with Solvay Minerals in its Wyoming operation (Industrial Minerals, 2000b).

Pakistan.—ICI Pakistan, Ltd., which was owned by ICI plc (76%) and private investors (24%), announced a $10 million expansion at its synthetic soda ash plant in Khewara, northern Punjab. The expansion would increase the facility's capacity from 190,000 t/yr to 225,000 t/yr. The operation supplied about 80% of the domestic soda ash requirements of the country's detergent, glass, and paper industries (Industrial Minerals, 2000c).

Outlook

As the 20th century drew to a close, the number of producers in the world soda ash industry became smaller because of the closures of many synthetic soda ash plants in Europe, South America, and Asia during the 1990s. At the beginning of the new millennium, three dominant groups have survived to become the world leaders in soda ash—Solvay S.A. of Belgium, ANSAC of the United States (which represents all six domestic producers), and the Chinese soda ash industry. In years to come, these three soda ash suppliers will produce and export soda ash to many customers all over the world. Because the glass container sector is the largest soda-ash-consuming sector, the demand for soda ash for glass containers may decline as consumers slowly accept their food and beverages packaged in the newer PET containers.

The outlook for soda ash for the next 5 years is favorable. Domestic soda ash is expected to grow between 0.5% and 1.0% per year, and world demand is forecast to range from 2.0% to 2.5% per year for the next several years. Asia and South America remain the likeliest areas for increased soda ash consumption in the near future.

TABLE 2
U.S. PRODUCERS OF SODA ASH IN 2000

(Million short tons, unless otherwise noted)

Company	Plant nameplate capacity	Plant location	Source of sodium carbonate
American Soda, L.L.P. 1/	1.00	Parachute, CO	Underground nahcolite.
FMC Wyoming Corp. - Green River 2/	3.55	Green River, WY	Underground trona.
FMC Wyoming Corp. - Granger 3/	1.30	Granger, WY	Do.
General Chemical (Soda Ash) Partners 4/	2.80	Green River, WY	Do.
IMC Chemical Co. 5/	1.45	Trona, CA	Dry lake brine.
OCI Chemical Corp. 6/	3.10	Green River, WY	Underground trona.
Solvay Minerals Inc. 7/	2.80	do.	Do.
Total	16.00		
Total million metric tons	14.50		

1/ Came on-stream October 2000. A joint venture with Williams Sodium Products Co., which is a subsidiary of The Williams Companies, Inc. (60%), and American Alkali, Inc. (40%).

2/ Formed joint venture (20%) in February 1996 with Sumitomo Corp. and Nippon Sheet Glass Co., Ltd., both of Japan.

3/ Tg Soda Ash Inc. was sold to FMC Wyoming Corp. in July 1999.

4/ A joint venture between General Chemical Corp. (51%), Owens-Illinois, Inc. [acquired Australian Consolidated Industries International (ACI) in 1998] (25%), and TOSOH Wyoming Inc. of Japan (24%), which purchased part of ACI's share in June 1992. An expansion was completed in 1998.

5/ IMC Global, Inc., acquired North American Chemical Co. in April 1998; operation renamed.

6/ Rhône-Poulenc Basic Chemicals Co. of France sold its 51% share to Oriental Chemical Industries Chemical Corp. of Korea on February 29, 1996; Anadarko Petroleum Corp. (acquired Union Pacific Resources Co. in 2000) owns 49%. An 800,000-metric-ton expansion, brought on-stream in November 1998, increased plant capacity to 3.1 million short tons; however, the company planned to take 900,000 metric tons out of service temporarily for equipment refurbishment.

7/ Solvay Soda Ash Joint Venture is owned by Solvay S.A. of Belgium (80%) and Asahi Glass Co. of Japan (20%), which became a partner in February 1990. Capacity increase of 272,000 metric tons (300,000 short tons) installed December 1995 and 454,000 metric tons (500,000 short tons) in October 2000.

STONE, CRUSHED

By Valentin V. Tepordei

Domestic survey data and tables were prepared by Susan M. Copeland and John G. Durand, statistical assistants.

Crushed stone, one of the most accessible natural resources, is a major basic raw material used by construction, agriculture, and other industries that use complex chemical and metallurgical processes. Despite the low value of its basic products, the crushed stone industry is a major contributor to and an indicator of the economic well-being of the Nation.

A total of 1.56 billion metric tons (Gt) of crushed stone was produced for consumption in the United States in 2000, a 30-million-metric-ton (Mt) or 2.0% increase compared with the total production of 1999. This tonnage represents the highest production level ever recorded in the United States, indicating a continued increase in the demand for construction aggregates (table 1).

About 70% of crushed stone production continued to be limestone and dolomite, followed, in descending order of tonnage, by granite, traprock, sandstone and quartzite, miscellaneous stone, marble, slate, calcareous marl, shell, and volcanic cinder and scoria (table 2).

Foreign trade of crushed stone continued to remain small. Exports decreased by 2.4% to 4 Mt, and their value decreased by 3.6% to $29.7 million compared with that of 1999 (table 25).

Imports of crushed stone, including calcium carbonate, increased by 5.7% to 13 Mt, but the value decreased by 0.5% to $105 million (table 26). Domestic apparent consumption of crushed stone, which is defined as production for consumption (sold or used) plus imports minus exports, was 1.57 Gt (tables 1, 25, 26).

Legislation and Government Programs

The Aviation Investment and Reform Act for the 21st Century (Public Law 106-181) was signed by the President on April 5, 2000. The law is a 3-year reauthorization of Federal Aviation Administration (FAA) programs and releases an estimated $1.9 billion in fiscal year 2000 for the Airport Improvement Program (AIP). In the following 3 years, the AIP funding will increase as follows: to $3.2 billion in fiscal year 2001, $3.3 billion in fiscal year 2002, and $3.4 billion in fiscal year 2003. In addition to the AIP, funds are also included for air traffic control improvements, airport security, noise abatement programs, and environmental streamlining programs. The law restructures and reauthorizes programs of the FAA and ensures that the taxes travelers pay on airline tickets are used to maintain the aviation system as originally intended.

On September 13, 2000, the Mine Safety and Health Administration (MSHA) regulation named "Health Standards for Occupational Noise Exposure—30 CFR Parts 56, 57, 62, 70, and 71" became effective. This final comprehensive rule replaced MSHA's previous standards for occupational noise exposure in coal mines and metal and nonmetal mines. The final rule established uniform requirements to protect the Nation's miners from occupational noise-induced hearing loss. The rule is derived in part from existing MSHA noise standards and from the Department of Labor's existing occupational noise exposure standard for general industry promulgated by the Occupational Safety and Health Administration. As a result of the ongoing review of its safety and health standards, the MSHA determined that its noise standards, which were more than 20 years old, did not adequately protect miners from occupational noise-induced hearing loss.

On October 2, 2000, the MSHA final rule titled "Training and Retraining of Miners Engaged in Shell Dredging or Employed

Crushed Stone in the 20th Century

At the beginning of the 20th century, the production of crushed stone in the United States was relatively small, and the uses of this resource were limited. At that time, records of stone production were kept on the basis of value, without recording the tonnages produced and without making a distinction between crushed and dimension stone. The value of all stone produced in the United States in 1900 was $43.8 million. In 1916, the U.S. Geological Survey reported for the first time quantities as well as values of domestic crushed stone production—77 million metric tons worth $50 million. In 1900, stone was used for construction purposes, mainly roads and buildings, for cement and lime manufacturing, for agricultural purposes as a soil treatment agent, and as flux stone in steel manufacturing. Stone production was reported in all 45 States. Leading States, in order of total value of production, were Pennsylvania, Vermont, Ohio, New York, and Maine. Vermont and Maine were among the top 5 States, probably because a significant amount of dimension stone, which was always more valuable than crushed stone, was being produced in those States.

In 2000, a total of 1.56 billion metric tons of crushed stone valued at $8.4 billion was produced in the United States for consumption, the highest production level ever recorded, indicating a continued increase in the demand for construction aggregates. About 70% of the crushed stone produced was limestone and dolomite, followed, in descending order of tonnage, by granite, traprock, sandstone and quartzite, miscellaneous stone, marble, slate, calcareous marl, shell, and volcanic cinder and scoria. About 84% of the total crushed stone produced by 1,500 companies operating 3,800 active quarries in 49 States was used as construction aggregates, mostly for highway and road construction and maintenance; 13%, for chemical and metallurgical uses, including cement and lime manufacture; 2%, for agricultural uses; and 1%, for special uses and products. Leading States, in order of production, were Texas, Florida, Pennsylvania, Illinois, Georgia, Missouri, Ohio, North Carolina, Virginia, and Tennessee, together accounting for 51% of the total output. Foreign trade in crushed stone was very small throughout the century, compared to the total U.S. production.

Digitized by Google

at Sand, Gravel, Surface Stone, Surface Clay, Colloidal Phosphate, or Surface Limestone Mines—30 CFR Parts 46 and 48" became effective. This final rule amends MSHA's existing health and safety training regulations by establishing new training requirements for shell dredging, sand, gravel, surface stone, surface clay, colloidal phosphate, and surface limestone mines. This final rule implements the training requirements of section 115 of the Federal Mine Safety and Health Act of 1997 and provides for effective miner training at the affected mines. At the same time, the final rule allows mine operators the flexibility to tailor their training programs to the specific needs of their miners and operations.

Production

Domestic production data for crushed stone are derived by the U.S. Geological Survey (USGS) from voluntary surveys of U.S. producers. Of the 4,432 crushed stone operations on the mailing list, 3,453 operations with 3,577 quarries owned by 1,367 companies were active. Of the 3,453 active operations, 2,705 operations with 2,791 quarries, representing 78.3% of the total number of active operations, reported to the USGS. Their total production represented 85.3% of the total U.S. crushed stone output. It should be noted that a total of 146 sales yards were active in 2000 in 24 States (table 24). Of the 2,705 reporting operations with 2,791 quarries, 921 operations with 863 quarries and 58 sales yards owned by 139 companies did not report a breakdown by end use. Their production represented 29.6% of the U.S. total and is included in table 13 under "Unspecified, reported" uses. The nonrespondents' production was estimated by using employment data and/or adjusted production reports from prior years. The estimated production from 748 nonresponding operations with 786 quarries owned by 537 companies represented 14.7% of the U.S. total and is included in table 13 under "Unspecified, estimated" uses. Information regarding the number of active operations, active quarries, type of processing plants, and number of sales yards by State is provided in table 24.

A total of 77 underground mines that are included in the total number of active operations produced 48.2 Mt of crushed stone in 2000. Active underground mines were in 15 States. The five leading States, in descending order of tonnage, were Kentucky, Nebraska, Illinois, Iowa, and Indiana. Their production represented 21.7% of the total U.S. crushed stone produced underground.

A total of 933 quarries were either idle or presumed to have been idle in 2000 because no information was available to estimate their production. Since the 1999 survey, 64 operations were closed down. Most of the idle or closed operations were small, temporary quarries, some of them operated by State or local governments. Operations in U.S. territories are not included in the above count.

Of the total 1.56 Gt of crushed stone produced for consumption in the United States in 2000, 1.1 Gt, or 70.4%, was limestone and dolomite; 246 Mt, or 15.8%, was granite; and 114 Mt, or 7.3%, was traprock. The remaining 111 Mt, or 6.5%, was shared, in descending order of quantity, by sandstone and quartzite, miscellaneous stone, marble, calcareous marl, slate, shell, and volcanic cinder and scoria (table 2).

A comparison of the four geographic regions of the United States indicates that, in 2000, the South continued to lead the Nation in the production of crushed stone with 745 Mt, or 47.8% of the total; followed by the Midwest with 444 Mt, or 28.5%; and the Northeast with 207.7 Mt, or 13.3%. About 76% of the total U.S. crushed stone output was produced in the South and the Midwest (table 3).

Of the nine geographic divisions, as shown in figure 1, the South Atlantic led the Nation in the production of crushed stone with 385 Mt, or 24.7% of the U.S. total. It was followed by the East North Central division with 281 Mt, or 18.0%; and the West South Central division with 191 Mt, or 12.2%.

Crushed stone was produced in every State except Delaware. The 10 leading producing States, in descending order of tonnage, were Texas, Pennsylvania, Florida, Georgia, Illinois, Missouri, Ohio, North Carolina, Virginia, and Tennessee. Their combined production represented 52.2% of the national total.

Leading U.S. producing companies, in descending order of tonnage, were Vulcan Materials Co.; Martin Marietta Aggregates; Hanson Building Materials America; Oldcastle, Inc./Materials Group; CSR America, Inc.; Lafarge Corp.; Rogers Group, Inc.; Florida Rock Industries, Inc.; CEMEX, Inc.; and Oglebay Norton Co.

A review of production by size of operation at the national level indicates that in 2000, 846.6 Mt, or 54.3% of total crushed stone, was produced by 477 operations reporting more than 1 million metric tons per year; 384.6 Mt, or 24.6%, was produced by 588 operations reporting between 500,000 and 999,999 metric tons per year (t/yr); and 325.7 Mt, or 20.9%, was produced by operations reporting less than 500,000 t/yr (table 7).

In 2000, consolidation in the aggregates industry continued but at a slower pace. Most of the acquisitions were made by the major producers of aggregates, most of which were publicly owned. These companies tried to expand their base of operations in new areas of the country or acquired operations or companies with significant amounts of reserves. Stricter environmental and permitting regulations make it more difficult to start a new operation than to acquire an existing one. Some of the acquired companies continue to operate as semi-independent organizations but with the benefit of financial and managerial support provided by the larger new owner.

Effective January 1, 2000, Seattle-based Lone Star Northwest changed its name to Glacier Northwest because the company is no longer part of Lone Star Industries, Inc., and did not own the rights to use the Lone Star name (Rock Products, 2000a).

In January, Vulcan Materials Co. of Birmingham, AL, announced the purchase of Garves W. Yates & Sons Co. located in Abilene, TX. The purchase included six quarry sites and four portable aggregates plants. Kiewit Materials Co. of Omaha, NE, acquired Solano Concrete Co., Inc. The company operates a quarry and an aggregates producing plant located in northern California (Rock Products, 2000j).

Also in January, Aggregates Industries, Inc., announced that all its U.S. divisions will now be operating under the Aggregates Industries name. The name change symbolizes the evolution of Aggregates Industries into a unified U.S. company. The divisions affected by the name change include: U.S. Bardon Trimount of Saugus, MA; Bardon Mid-Atlantic of Greenbelt, MD; CAMAS Colorado of Denver, CO; CAMAS Minnesota of Minneapolis, MN; CAMAS Minndak of Fargo, ND; and Bill Smith Sand and Gravel Co. of Otsego, MI. The name change will also be applied to all Aggregates Industries operating businesses in the United Kingdom (Rock Products, 2000b).

In February, Oldcastle Materials Group of Washington, DC, announced the acquisition of The Shelly Co. of Thornville, OH, which operates 3 quarries and 10 sand and gravel pits and supplies markets in southern Ohio and in West Virginia.

Digitized by Google

Shelly's aggregates reserves are estimated to be more than 200 Mt (Rock Products, 2000c). Martin Marietta Materials, Inc., of Raleigh, NC, announced the acquisition of the Pennry Stone Co., which operates a limestone quarry north of Columbus, OH, and another limestone quarry at Philippi, WV (Rock Products, 2000h). Aggregates Industries, Inc., of Bethesda, MD, acquired Holst Excavating Co., which operates five limestone quarries and two sand and gravel pits southeast of Minneapolis/St. Paul, MN. Permitted reserves of Holst Excavating Co. are estimated to be more than 200 Mt (Rock Products, 2000a).

On February 14, Graniterock Co. of Watsonville, CA, celebrated its 100th year in business as a family-owned crushed stone producer. In 1993, Graniterock received the Baldridge Award that was created by the U.S. Congress to raise awareness about quality management practices. For the 3 consecutive years between 1997 and 1999, Graniterock Co. was named by Fortune Magazine one of the 100 best companies to work for (Rock Products 2000e).

In June, CSR America of West Palm Beach, FL, announced the acquisition of American Limestone Co. and of Florida Crushed Stone Co. These two acquisitions increased CSR America's production capacity by about 50%, as well as its aggregates reserves (Rock Products, 2000d).

In July, Martin Marietta Materials, Inc., announced that it acquired from A.B. Long Quarries a limestone quarry located near Knoxville, TN, and also signed a long-term contract to process aggregates and assume all responsibility for an operation at Chemical Lime Co.'s New Braunfels, TX, facility. The company also announced that it purchased the Texarkana Asphalt operation, which has a rail-served aggregates distribution yard in Texarkana, TX, and a rail-distribution yard near Wilmington, NC (Rock Products, 2000i). Lafarge Corp. of Hearndon, VA, announced the purchase from Presque Isle Corp. of a limestone quarry located in Presque Isle, MI, about 20 miles (about 34 kilometers) north of Alpena on the shore of Lake Huron, where Lafarge already operates a large quarry and a cement manufacturing plant (Rock Products, 2000f).

In August, Titan Cement S.A. agreed to purchase Tarmac-America, Inc., and subsequently sold all Tarmac America's non-Florida aggregates operations to Vulcan Materials. These operations included four quarries in South Carolina, the Hanover Quarry in Pennsylvania, three quarries and three sand and gravel pits in Virginia, and distribution and marine operations in Maryland and Virginia (Rock Products, 2000k).

U.S. Aggregates announced that it expanded the distribution of aggregates products with a startup of a major sales yard in Memphis, TN, three new yards in Mississippi, and two new yards in the Florida panhandle (Rock Products, 2000l).

In September, Martin Marietta Materials, Inc., announced that under the terms of the October 1998 investment agreement between the two companies, it would buy the remaining part of Meridian Aggregates Co. that it did not already own (Pit & Quarry, 2000b).

In October, CEMEX S.A. de C.V. and Southdown announced that the two companies entered into a definitive merger agreement under which CEMEX would acquire all of the outstanding stock of Southdown. Later that month, it was announced that the merger was completed successfully (Pit & Quarry, 2000a). Global Stone Corp. of Roswell, GA, a wholly owned subsidiary of Oglebay Norton Co., has acquired the assets of the J.M. Huber Corp. limestone processing facility located near Portage, IN. The facility will be known as Global Stone Portage LLC and will use high-quality limestone from their Michigan limestone quarries (Pit & Quarry, 2000c).

After receiving approval votes from most of their member companies, effective September 30, 2000, the National Aggregates Association and the National Stone Association merged to form the National Stone, Sand & Gravel Association. The new association will be the sole organization representing the crushed stone and sand and gravel producing companies at the national level.

Limestone.—The 2000 output of crushed limestone, including some dolomite, increased by 2.6% to 998 Mt valued at $5.0 billion compared with the revised 1999 totals (table 2).

Limestone was produced by 767 companies at 1,965 operations with 1,955 quarries in 47 States. In addition, 38 companies with 50 operations and 52 quarries reported producing limestone and dolomite from the same quarries. Their production of 35.4 Mt is included with the limestone listed in table 2. The limestone totals listed in this chapter, therefore, include an undetermined amount of dolomite in addition to the dolomite reported separately.

The leading producing States, in descending order of tonnage, were Texas, Florida, Missouri, Ohio, and Pennsylvania; these five States accounted for 40% of the total U.S. output (table 8). The leading producers of limestone, in descending order of tonnage, were Martin Marietta Aggregates, Inc.; Vulcan Materials Co; Hanson Building Materials America; Lafarge Corp.; and CSR America.

Dolomite.—Production of dolomite decreased by 1.9% to 101 Mt valued at $533 million compared with the revised 1999 totals (table 2). Crushed dolomite was reportedly produced by 96 companies at 174 operations with 191 quarries in 29 States. An additional undetermined amount of dolomite is included in the total crushed limestone, as explained above.

The leading producing States, in descending order of tonnage, were Illinois, Pennsylvania, Indiana, Ohio, and New York; these five States accounted for 57.1% of the total U.S. output (table 8). The leading producers, in descending order of tonnage, were Oldcastle, Inc./Materials Group; General Dynamics Group; S.E. Johnson Companies, Inc.; Vulcan Materials Co.; and Hanson Building Materials America.

Marble.—Production of crushed marble increased by 6.8% to 11 Mt valued at $64.8 million, compared with the revised figure for 1999 (table 2). Crushed marble was produced by 14 companies with 23 operations and 28 quarries in 11 States (table 9). The leading producers of crushed marble, in descending order of tonnage, were Imerys Marble, Inc.; Florida Rock Industries, Inc.; Pluess Staufer, Inc.; Geogia Marble Stone Corp.; and Vulcan Materials Co.

Calcareous Marl.—Output of marl increased by 3.9% to 3.7 Mt valued at $16.6 million, compared with the 1999 totals (table 2). Marl was produced by seven companies with seven operations and seven quarries in five States (table 9). The leading producers, in descending order of tonnage, were Holderbank/Holman, Inc.; Capitol Aggregates LTD; and Giant Group Ltd.

Shell.—Shell is derived mainly from fossil reefs or oyster shell banks. The output of crushed shell decreased by 1.7% to 1.8 Mt valued at $8.6 million compared with the revised 1999 totals (table 2). Crushed shell was produced by 11 companies with 11 operations in 7 States. The leading producers, in descending order of tonnage, were Caloosa Shell Corp.; Schroeder Manatee, Inc.; and F&W Mines, Inc.

Granite.—The output of crushed granite increased by only 0.8% to 246 Mt valued at $1.6 billion, compared with the revised 1999 totals (table 2). Crushed granite was produced by 139 companies at 375 operations with 369 quarries and 6 sales

Digitized by Google

yards in 34 States.

The leading States, in descending order of tonnage, were Georgia, North Carolina, Virginia, South Carolina, and California; these five States accounted for 72.5% of the U.S. output (table 10). The leading producers, in descending order of tonnage, were Vulcan Materials Co., Martin Marietta Aggregates, Hanson Building Materials America, Meridian Aggregates Co., and Florida Rock Industries, Inc.

Traprock.—Production of crushed traprock increased by 1.8% to 114 Mt valued at $724 million, compared with the revised 1999 total (table 2). Traprock was produced by 226 companies at 349 operations with 445 quarries in 24 States.

The leading producing States, in descending order of tonnage, were Oregon, New Jersey, Virginia, Washington, and California; these five States accounted for 61.1% of U.S. output (table 10). Leading producers, in descending order of tonnage, were Oldcastle, Inc./Materials Group; Vulcan Materials Co.; Luck Stone Corp.; Stavola, Inc.; and Eucon Co.

Sandstone and Quartzite.—The combined output of crushed sandstone and quartzite increased by 4.8% to 43.6 Mt, valued at $255 million compared with the revised 1999 totals (table 2). Crushed sandstone was produced by 118 companies at 153 operations with 151 quarries in 24 States, and crushed quartzite was produced by 37 companies at 45 operations with 49 quarries in 17 States.

The leading producing States, in descending order of tonnage of sandstone and quartzite, were Pennsylvania, Arkansas, California, Oklahoma, and South Dakota; their combined production accounted for 56.6% of the U.S. output (table 10). The leading producers of sandstone, in descending order of tonnage, were Lafarge Corp.; Ashland Oil, Inc./APAC, Inc.; and Martin Marietta Aggregates. The leading producers of quartzite were Martin Marietta Aggregates; County Line Quarry, Inc.; and Salem Stone Corp.

Slate.—The output of crushed slate decreased by 18.3% to 2.8 Mt valued at $19.1 million compared with the revised 1999 totals (table 2). Crushed slate was produced by 13 companies at 14 operations with 18 quarries in 10 States.

Most of the crushed slate was produced in North Carolina. The leading producers, in descending order of tonnage, were Martin Marietta Aggregates; McCartney Construction Co., Inc., and NAPA Development Corp., Inc.

Volcanic Cinder and Scoria.—Production of volcanic cinder and scoria decreased by 14.6% to 1.8 Mt valued at $13.2 million compared with the 1999 totals (table 2). Volcanic cinder and scoria were produced by 22 companies from 38 operations with 39 quarries in 12 States.

The leading producing States, in descending order of tonnage, were California, Washington, and Texas (table 11). Leading producers, in descending order of tonnage, were Martin Marietta Aggregates; Peter Kiewit Sons', Inc.; and Bishop Red Rock, Inc.

Miscellaneous Stone.—Output of other kinds of crushed stone decreased by 0.6% to 32.5 Mt valued at $191 million compared with the revised 1999 totals (table 2). Miscellaneous stone was produced by 124 companies at 250 operations with 265 quarries in 28 States.

The leading producing States, in descending order of tonnage, were Pennsylvania, California, and Texas; their combined production accounted for 41.1% of the total U.S. output. Leading producers, in descending order of tonnage, were the U.S. Department of Agriculture's Forest Service; the U.S. Department of the Interior's Bureau of Land Management; U.S. Silica Co.; Aggregates Industries, Inc.; and RMC Group.

Consumption

Crushed stone production reported to the USGS is actually material that was either sold or used by producers. Production that was stockpiled is not included in the reported quantities. The "sold or used" tonnage, therefore, represents the amount of production released for domestic consumption or export in a given year. Because some of the crushed stone producers did not report a breakdown by end use, their total production is included in "Unspecified, reported" use. The estimated production of nonrespondents is included in the "Unspecified, estimated" use.

In 2000, U.S. consumption of crushed stone was 1.56 Gt, a 2.0% increase compared with the revised consumption of 1999. This total is slightly different from the "apparent consumption" of crushed stone that is defined as "U.S. production plus imports minus exports." Of the 1.56 Gt of crushed stone consumed, 691 Mt, or 44.3% of the total, was "Unspecified, reported and estimated" uses. Of the remaining 869 Mt, reported by uses, about 82.3% was used as construction aggregates, mostly for highway and road construction and maintenance; 14.6%, for chemical and metallurgical uses, including cement and lime manufacture; 1.5%, for agricultural uses; and 0.7%, for special uses and products (table 13). To provide a more accurate estimation of the consumption patterns for crushed stone, the "Unspecified" uses are not included in the above percentages. In any use pattern study or marketing analysis, the quantities included in the "Unspecified" uses should be distributed among the reported uses by applying the above percentages to the total of the "Unspecified" uses.

Limestone.—Of the 998 Mt of crushed limestone consumed, 445 Mt, or 44.6%, was in "Unspecified, reported and estimated" uses. Of the remaining 553 Mt of crushed limestone, reported by uses, 75.8% was used as construction aggregates; 21.5%, for chemical and metallurgical applications including cement and lime manufacturing; 2%, for agricultural uses; and 0.8%, for special uses and products (table 14).

Dolomite.—Of the 101 Mt of crushed dolomite consumed, 45.1 Mt, or 44.7%, was in "Unspecified, reported and estimated" uses. Of the remaining 55.9 Mt of crushed dolomite, reported by uses, 91.2% was used as construction aggregates; 3.9%, for chemical and metallurgical applications; and 3.8%, for agricultural uses. An additional undefined amount of dolomite consumed in a variety of uses, mostly construction aggregates, is reported with the limestone (table 14).

Marble.—Of the 11 Mt of crushed marble consumed, 9.2 Mt, or 83.7%, was reported as "Unspecified, reported and estimated" uses. The remaining 1.8 Mt of crushed marble, reported by uses, was used as construction aggregates and for special and miscellaneous uses, including fillers and extenders (table 16).

Calcareous Marl.—Of the 3.7 Mt of crushed calcareous marl consumed, 3.6 Mt, or 97.3%, was used for cement manufacturing.

Shell.—Of the 1.8 Mt of crushed shell consumed, 199,000 metric tons (t), or 11%, was reported as "Unspecified, reported and estimated" uses. Most of the remaining 1.78 Mt was used as construction aggregates.

Granite.—Of the 246 Mt of crushed granite consumed, 99 Mt, or 40.2%, was reported as "Unspecified, reported and estimated" uses. Of the remaining 147 Mt, most was used as construction aggregates (table 17).

Traprock.—Of the 114 Mt of crushed traprock consumed, 55.1 Mt, or 48.3%, was reported as "Unspecified, reported and

Digitized by Google

estimated" uses. Of the remaining 58.9 Mt, most was used as construction aggregates (table 17).

Sandstone and Quartzite.—Of the 33 Mt of crushed sandstone consumed, 16 Mt, or 48.5%, was reported as "Unspecified, reported and estimated" uses. Of the remaining 17 Mt of crushed sandstone reported by uses, 15.4 Mt, or 90.6%, was used as construction aggregates (table 18).

Of the 10.6 Mt of crushed quartzite consumed, 3.7 Mt, or 34.9%, was reported as "Unspecified, reported and estimated" uses. Of the remaining 6.9 Mt of crushed quartzite, reported by uses, 5.7 Mt, or 83.3%, was used as construction aggregates (table 18).

Volcanic Cinder and Scoria.—Of the 1.8 Mt of volcanic cinder and scoria consumed, 677,000 t, or 38.5%, was reported as "Unspecified, reported and estimated" uses. Most of the remaining 1.1 Mt of crushed volcanic cinder and scoria was used as construction aggregates (table 19).

Miscellaneous Stone.—Of the 35.3 Mt of miscellaneous crushed stone consumed, 22.2 Mt, or 62.9%, was reported as "Unspecified, reported and estimated" uses. Of the remaining 13.1 Mt reported by uses, 12 Mt, or 91.9%, was used as construction aggregates.

Additional information regarding production and consumption of crushed stone by type of rock and major uses in each State and the State districts may be found in the USGS Minerals Yearbook, volume II, Area Reports: Domestic.

Recycling

As the recycling of most waste materials increases, aggregates producers are recycling more cement concrete and asphalt concrete materials recovered from construction projects to produce concrete aggregates and asphalt aggregates. The annual survey of crushed stone producers now collects information on recycling of cement and asphalt concretes produced by the crushed stone producers only. Information on recycling of these materials by construction or demolition companies is not collected by the USGS.

Asphalt Concrete.—A total of 1.3 Mt of asphalt concrete valued at $7.3 million was recycled by 56 companies in 23 States. This volume represents a 12.4% decrease compared with that of 1999 (tables 20, 21). The leading recycling States, in descending order of tonnage, were California, Wisconsin, and Pennsylvania. The leading recycling companies, in descending order of tonnage produced, were Holmes Construction Co., Inc.; Raisch Products; and Stone Industries, Inc.

Cement Concrete.—A total of 2.3 Mt of cement concrete valued at $13.9 million was recycled by 51 companies in 25 States. This tonnage represents a 34.1% increase compared with that of 1999 (tables 20-22). The leading recycling States, in descending order of tonnage, were Illinois, California, New Jersey, and Florida. The leading companies, in descending order of tonnage produced, were Vulcan Materials Co.; Stone Industries, Inc.; and Dolomite Products.

Prices

Prices in this chapter are average free on board (f.o.b.) plant, usually at the first point of sale or captive use, as reported by the companies. This value does not include transportation from the plant or yard to the consumer. It does, however, include all costs of mining, processing, inplant transportation, overhead costs, and profit.

The average unit price per ton of crushed stone increased slightly by 0.6% to $5.39 compared with that of 1999. The average unit prices, by kind of stone, increased between 0.7% for limestone and 18.8% for volcanic cinder and scoria and decreased by 0.4% for calcareous marl (table 2).

Transportation

For 722 Mt, or 46.3%, of the 1.56 Gt of crushed stone produced for consumption in 2000, no means of transportation was reported by the producers. Of the remaining 838 Mt of crushed stone, 639 Mt, or 76.3%, was reported as being transported by truck from the processing plant or quarry to the first point of sale or use; 56.7 Mt, or 6.8%, by rail; and 38.6 Mt, or 4.6%, by waterway. About 9% of the specified production was reported as not having been transported and, therefore, is assumed to have been used onsite. Information regarding means of transportation used by the producers to ship crushed stone in each geographic region is provided in table 23.

Foreign Trade

The widespread distribution of domestic deposits of stone suitable for mining as crushed stone and the high cost of transportation limits foreign trade to mostly local transactions across international boundaries. U.S. imports and exports are small, representing less than 1% of domestic consumption. Shipments of crushed stone by water from Canada and especially Mexico, however, continue to increase.

Exports.—Exports of crushed stone decreased by 2.4% to 4 Mt compared with those of 1999, and the value decreased by 3.6% to $29.7 million. About 97% of the exported crushed stone was limestone for cement manufacturing. Canada was the major destination with 99.7% of the total crushed stone (table 25).

Imports.—Imports of crushed stone, including calcium carbonate fines, increased by 5.7% to 13 Mt compared with those of 1999, and the value decreased by 0.9% to $105 million. About 88% of the imported crushed stone was limestone. Imports of natural calcium carbonate fines remained unchanged from the previous year at 1,000 t, while the value increased by 111% to $698,000 (table 26).

Shipments of crushed stone from The Bahamas, Canada, and Mexico into the United States continued in 2000. The imported crushed stone was used mostly as construction aggregates or for cement manufacturing. This trend is expected to continue, and the volume of imports, especially from Mexico, is expected to increase.

Outlook

The demand for crushed stone in 2001 is expected to be about 1.6 Gt, a 2.5% increase compared with 2000. Gradual increases in demand for construction aggregates are anticipated after 2000 as well, based on the expected volume of work on the infrastructure that will be financed by the new Transportation Equity Act for the 21st Century, the Aviation Investment and Reform Act for the 21st Century, and the U.S. economy in general. The projected increases will be influenced by the construction activity in the public and private construction sectors, as well as by the new construction work related to security measures being implemented around the Nation. Crushed stone f.o.b. prices are not expected to increase significantly. The delivered prices of crushed stone, however, are expected to increase, especially in and near metropolitan

Digitized by Google

areas, mainly because more aggregates are transported from distant sources.

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ To avoid disclosing company proprietary data, certain State totals do not include all kinds of stone produced within the State; the portion not shown has been included with "Other."
3/ Data derived, in part, from Alaska Division of Geological and Geophysical Surveys information.
4/ Excludes limestone-dolomite.
5/ Excludes slate.
6/ Excludes shell.
7/ Excludes marble.
8/ Excludes sandstone.
9/ A significant amount of sold or used material was shipped in from other States.
10/ Excludes limestone.
11/ Excludes traprock.
12/ Excludes calcareous marl.
13/ Excludes miscellaneous stone.
14/ Excludes volcanic cinder and scoria.
15/ Excludes dolomite.

Total	XX	XX	XX	XX	XX	XX	XX	XX	1,560,000	8,550,000

XX Not applicable. -- Zero.

1/ As published in the "Crushed Stone and Sand and Gravel in the Fourth Quarter of 2000" chapter of the Mineral Industry Surveys.

2/ Quarterly totals shown are estimates based on a sample survey. Estimated quantities for prior quarters have been recalculated.

3/ Data may not add to totals shown because of independent rounding and differences between projected totals by States and regions.

4/ All percentage changes are calculated by using unrounded totals. Percentage changes are based on the corresponding quarter of the previous year.

5/ State not included in quarterly survey.

6/ To avoid disclosing proprietary data, some State totals do not include all types of stone produced within the State; portion not shown has been included with "Other."

7/ Owing to the low number of companies, no production estimates by quarter were generated.

TABLE 13
CRUSHED STONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 2000, BY USE 1/

Use	Quantity (thousand metric tons)	Value (thousands)	Unit value
Construction:			
Coarse aggregate (+1½ inch):			
Macadam	8,130	$46,200	$5.68
Riprap and jetty stone	17,100	125,000	7.33
Filter stone	6,140	41,100	6.70
Other coarse aggregate	11,100	61,500	5.51
Coarse aggregate, graded:			
Concrete aggregate, coarse	93,000	612,000	6.58
Bituminous aggregate, coarse	75,000	518,000	6.90
Bituminous surface-treatment aggregate	15,600	107,000	6.87
Railroad ballast	10,800	59,500	5.50
Other graded coarse agggregate	79,600	482,000	6.06
Fine aggregate (-3/8 inch):			
Stone sand, concrete	21,900	134,000	6.10
Stone sand, bituminous mix or seal	16,200	97,700	6.01
Screening, undesignated	22,100	117,000	5.28
Other fine aggregate	31,300	159,000	5.08
Coarse and fine aggregates:			
Graded road base or subbase	136,000	689,000	5.06
Unpaved road surfacing	22,500	109,000	4.86
Terrazzo and exposed aggregate	1,660	16,400	9.89
Crusher run or fill or waste	35,100	171,000	4.86
Roofing granules	5,730	75,800	13.22
Other coarse and fine aggregates	92,800	461,000	4.97
Other construction materials 2/	13,400	81,100	6.06
Agricultural:			
Agricultural limestone	10,900	61,900	5.68
Poultry grit and mineral food	1,380	11,600	8.46
Other agricultural uses	1,010	8,450	8.35
Chemical and metallurgical:			
Cement manufacture	102,000	408,000	4.01
Lime manufacture	18,300	110,000	6.01
Dead-burned dolomite manufacture	658	3,200	4.87
Flux stone	4,010	19,600	4.87
Chemical stone	W	W	4.89
Glass manufacture	W	W	18.74
Sulfur oxide removal	2,250	10,200	4.54
Special:			
Mine dusting or acid water treatment	211	3,960	18.79
Asphalt fillers or extenders	1,450	13,200	9.10
Whiting or whiting substitute	1,030	22,200	21.51
Other fillers or extenders	2,990	43,700	14.63
Other miscellaneous uses:			
Abrasives	W	W	3.59
Flour (slate)	W	W	49.60
Sugar refining	W	W	12.97
Other specified uses not listed	2,250	12,600	5.60
Unspecified: 3/			
Reported	461,000	2,340,000	5.08
Estimated	230,000	1,100,000	4.94
Total	1,560,000	8,390,000	5.39

W Withheld to avoid disclosing company proprietary data; included in "Total."
1/ Data are rounded to no more than three significant digits, except unit values; may not add to totals shown.
2/ Includes acid neutralization, building products, drain fields, lightweight aggregate (slate), pipe bedding, and refractory stone.
3/ Reported and estimated production without a breakdown by end use.

W Withheld to avoid disclosing company proprietary data; included in "Total withheld" and "Total by State." XX Not applicable. -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ A significant amount of sold or used material was shipped in from other States.

3/ Withheld to avoid disclosing company proprietary data; included in "Grand total."

4/ Includes limestone-dolomite reported with no distinction between the two kinds of stone.

TABLE 16
CRUSHED MARBLE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 2000, BY USE

(Thousand metric tons and thousand dollars)

Use	Quantity	Value
Construction:		
Coarse aggregate (+1½ inch):		
Macadam	W	W
Riprap and jetty stone	W	W
Filter stone	W	W
Other coarse aggregate	3	22
Coarse aggregate, graded:		
Concrete aggregate, coarse	(2/)	(2/)
Bituminous aggregate, coarse	(2/)	(2/)
Bituminous surface-treatment aggregate	(2/)	(2/)
Other graded coarse aggregate	554	4,720
Fine aggregate (-3/8 inch):		
Screening, undesignated	(3/)	(3/)
Other fine aggregate	31	201
Coarse and fine aggregates:		
Graded road base or subbase	(4/)	(4/)
Terrazzo and exposed aggregate	(4/)	(4/)
Crusher run (select material or fill)	(4/)	(4/)
Other coarse and fine aggregates	456	2,510
Special, other fillers or extenders	W	W
Unspecified: 5/		
Reported	4,110	22,800
Estimated	5,100	29,000
Total	11,000	64,800

W Withheld to avoid disclosing company proprietary data; included in "Total."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Included with "Other graded coarse aggregate."
3/ Included with "Other fine aggregate."
4/ Included with "Other coarse and fine aggregates."
5/ Reported and estimated production without a breakdown by end use.

TABLE 17
CRUSHED GRANITE AND TRAPROCK SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 2000, BY USE 1/

(Thousand metric tons and thousand dollars)

Use	Granite		Traprock	
	Quantity	Value	Quantity	Value
Construction:				
Coarse aggregate (+1½ inch):				
Macadam	3,830	21,500	489	2,650
Riprap and jetty stone	2,370	24,800	1,500	13,500
Filter stone	1,300	12,300	824	5,400
Other coarse aggregate	1,880	9,190	852	5,100
Coarse aggregate, graded:				
Concrete aggregate, coarse	21,400	158,000	6,290	54,000
Bituminous aggregate, coarse	15,600	124,000	7,280	56,600
Bituminous surface-treatment aggregate	2,760	24,400	1,720	13,600
Railroad ballast	6,590	35,300	1,690	9,170
Other graded coarse aggregate	17,600	109,000	1,650	15,400
Fine aggregate (-3/8 inch):				
Stone sand, concrete	4,710	29,300	1,260	12,500
Stone sand, bituminous mix or seal	3,690	23,800	1,360	8,910
Screening, undesignated	5,480	28,600	1,960	13,000
Other fine aggregate	5,490	26,300	681	5,960
Coarse and fine aggregates:				
Graded road base or subbase	20,000	122,000	12,700	74,100
Unpaved road surfacing	712	4,190	1,840	8,960
Terrazzo and exposed aggregate	486	6,470	W	W
Crusher run or fill or waste	10,300	60,700	2,590	12,600
Other coarse and fine aggregates	17,700	94,300	10,000	55,600
Roofing granules	3,620	58,500	620	9,520

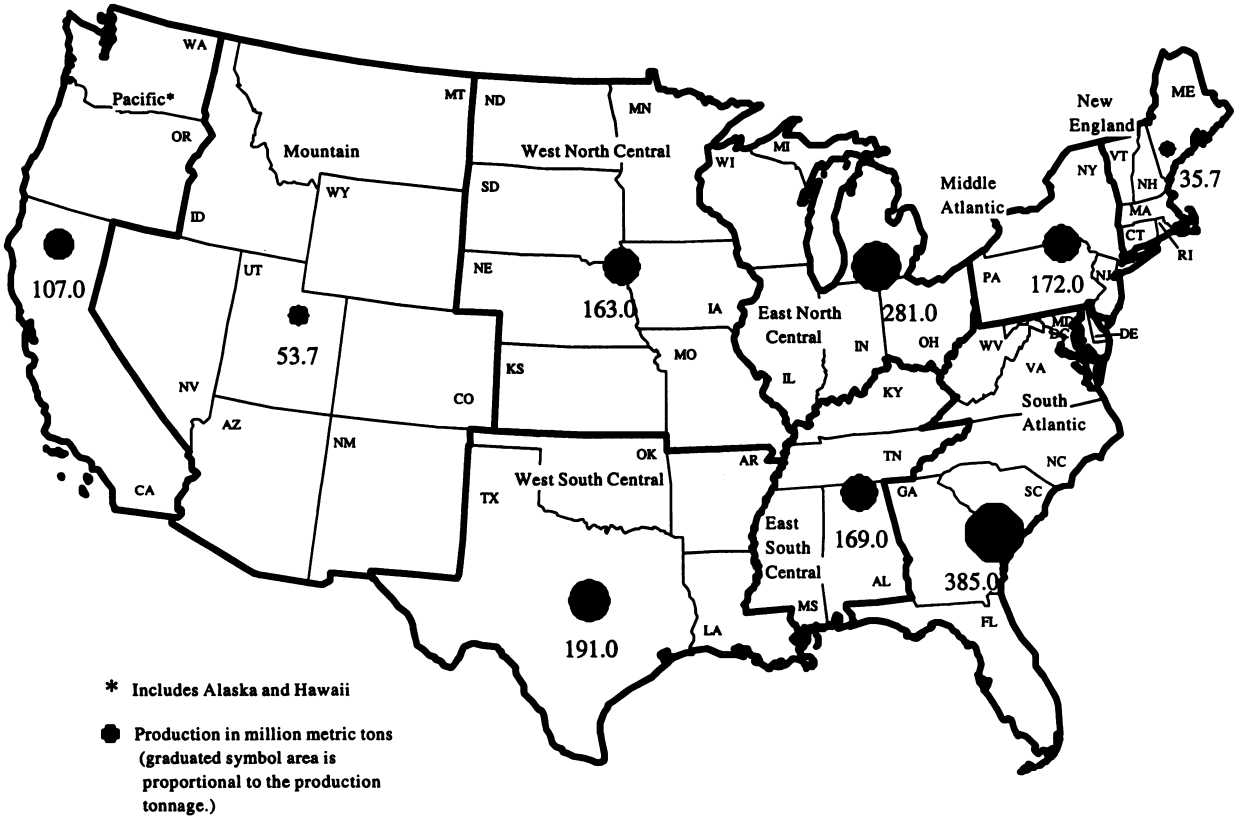
FIGURE 1
PRODUCTION OF CRUSHED STONE IN THE UNITED STATES IN 2000, BY GEOGRAPHIC DIVISION



Digitized by Google

STONE, DIMENSION

By Thomas P. Dolley

Domestic survey data and tables were prepared by Aaron J. Poyer, statistical assistant.

Dimension stone can be defined as natural rock material quarried for the purpose of obtaining blocks or slabs that meet specifications as to size (width, length, and thickness) and shape (Barton, 1968, p. 4). Color, grain texture and pattern, and surface finish of the stone are also normal requirements. Durability (essentially based on mineral composition and hardness and past performance), strength, and the ability of the stone to take a polish are other important selection criteria.

Although various igneous, metamorphic, and sedimentary rocks are used as dimension stone, the principal rock types are granite, limestone, marble, sandstone, and slate. Other varieties of dimension stone that are normally considered to be special minor types include alabaster (massive gypsum), soapstone (massive talc), and various products fashioned from natural stone.

U.S. production of dimension stone in 2000 was estimated to be 1.25 million metric tons (Mt) valued at $235 million—a 7% decrease in value compared with that of 1999. U.S. production of dimension stone in 2000 was the largest amount reported since 1993 and exceeded the 1999 amount by about 2,000 metric tons (t). Exports increased by 9.7% in value to $59.8 million, and imports for consumption increased by 14% in value to $925 million. Apparent consumption was estimated to be $1.1 billion.

In recent years, most dimension stone has been used in construction applications, with the largest portions being sold or used as rough block for building and construction, flagstone, curbing, and ashlars and partially squared pieces. Monumental stone, another major type, includes memorials of various kinds.

Dimension stone production data for the United States are derived by the U.S. Geological Survey (USGS) from a voluntary survey of U.S. quarry producers of rough and dressed dimension stone. Data in this report cover rough crude quarried stone, irregular-shaped and rectangular blocks, and more highly processed stone. A number of other terms also are used to describe further processing, such as "worked," "dressed," "finished," and "manufactured." These and other terms used by the dimension stone industry describe such features as the mineral composition of the rock, the shape of the product, the method of finishing a stone, and the type of finish applied (Stone World, 2000, p. 147-177). No adjustments are made in the data to account for the sometimes substantial losses in processing rough stone into dressed stone. Sold or used data are considered to be equivalent to production because changes in stocks are not surveyed. Of the 228 producing dimension stone operations included in the survey for 2000, 107 (or 47%) responded, which represented 58% of the tonnage; the remaining tonnage was estimated (table 1).

Description and Terminology

There are overlaps between scientific and commercial descriptions of various dimension stone types. The scientific description of dimension stone types is focused primarily on the stone's locality and mineralogical composition, whereas the commercial description is focused primarily on the locality and color of the stone. Furthermore, various combinations of the scientific and commercial descriptions are used by stone producers to effectively market their stone products. The descriptions that follow were adapted from Barton (1968, p. 2-8) and Currier (1960, p. 1-10).

Granite.—Commercial granites include all feldspathic crystalline rocks of mainly interlocking texture and with individual mineral grains that are visible to the naked eye. This category includes rock types such as gneiss, syenite, monzonite, granodiorite, anorthosite, and all other intermediate rock types. Primary colors of granites are white, gray, pink, and red, with green and brown being secondary colors. Black granites (which

Dimension Stone in the 20th Century

Punctuated by labor strikes and high costs and wages, production of all types of dimension stone in the United States in 1900 amounted to 1.6 million metric tons. The top producing State, by value, was Pennsylvania. In the early 20th century, reinforced concrete and structural steel superceded dimension stone as major structural components in buildings. As early as 1906, granite quarriers in the United States expressed concern over the encroachment of substitute materials, such as concrete, on their industry. With the emergence of the automobile, concrete and asphalt were viewed as more suitable materials than dimension stone for road building. In 1931, when the Empire State Building was officially opened, it featured cladding of Indiana limestone and helped in creating a new market for dimension stone as interior and exterior paneling. That same year, U.S. production of dimension stone rose to the highest level of the 20th century—more than 6 million tons. The lowest U.S. production of dimension stone of the 20th century occurred in 1944 during World War II at 649,000 metric tons, owing to a lack of skilled labor, nonessential commodity status, and building construction being at a virtual standstill.

In 2000, production of dimension stone in the United States amounted to about 1.3 million tons. The top producing State, by value, was Indiana. The United States was a significant importer of stone, importing dimension stone valued at more than $1 billion in 2000. Dimension stone was used extensively in home improvements, historic preservation, exterior and interior paneling for buildings, and construction applications. Most dimension stone was sold or used as rough blocks for building and construction, flagstone, curbing, ashlars and partially squared pieces, and monumental and memorial stones.

Digitized by Google

are not true granites mineralogically but rather such mafic rocks as diabases, diorites, gabbros, and similar rocks) are also included in this category and range in color from dark gray to black.

Limestone.—Commercial limestones are rocks of sedimentary origin primarily composed of calcium carbonate with or without magnesium. Included in this category are calcitic limestone, dolomite, dolomitic limestone, and travertine (a rock that is chemically precipitated from hot springs).

Marble.—Commercial marble includes metamorphosed limestones and serpentine rocks—all capable of taking a polish. An important member of this classification is serpentine marble, also known as verde antique, and is composed of green-to-black serpentine (a hydrous magnesium silicate mineral), crisscrossed by veins of lighter minerals such as calcite or dolomite.

Sandstone.—Commercial sandstone is a lithified sand composed chiefly of quartz or quartz and feldspar of fragmental (clastic) texture. Sandstone contains interstitial cementing materials, such as silica, iron oxides, calcite, or clay. Arkose (abundant feldspar grains), graywacke (abundant rock fragments), and conglomerates are included in this category. Other members of this category include bluestone (a dense, hard, fine-grained feldspathic sandstone, which splits easily along planes into thin, smooth slabs), brownstone (feldspathic sandstone of brown to reddish-brown color owing to abundant iron oxide), and flagstone (a sandstone or slate that splits into large, thin slabs).

Slate.—Commercial slate is a microgranular metamorphic rock formed by the recrystallization of clay sediments (shale, siltstone, or claystone). Characterized by excellent parallel cleavage, slates may be easily split into relatively thin slabs.

Greenstone.—Commercial greenstones are the result of the metamorphosis of basaltic rocks. Greenstone is named so because of the predominance of greenish minerals, such as chlorite, epidote, or actinolite.

Basalt and Traprock.—Commercial basalt and traprock includes igneous rocks that are too fine grained to be termed black granite. The name traprock is derived from the term "trappa," meaning stairway—the characteristic terraced or steplike appearance of certain basalt lava fields. This category includes both extrusive igneous rocks (such as andesite, basalt, or dacite) and intrusive igneous rocks (such as amphibolites, diabase, diorites, fine grained gabbros, peridotites, and pyroxenites).

Miscellaneous.—This category includes dimension stone types that do not easily fall into the aforementioned categories, such as soapstone, talc, or steatite (rocks containing various amounts of talc). Additional miscellaneous dimension stones include diatomite, mylonites, pumice, schist, tripoli, tuff, porous or scoriaceous volcanic rocks, or any other rocks used as building stones.

Production

Rough stone blocks split or cut from a quarry face are transported to processing plants, frequently located at the quarry site, at least for preliminary sizing. Further dressing, including final sizing and finishing operations, such as polishing, edging, and decorating, also may be done at the quarry site.

In 2000, limestone accounted for 432,000 t (or 35%) of the total domestic dimension stone production of 1.25 Mt, followed by granite (33%), sandstone (18%), miscellaneous stone (9%), marble (3%), and slate (2%). Granite accounted for about $112 million (or 48%) of total domestic production of $235 million, followed by limestone (28%), sandstone (10%), slate (6%), miscellaneous (5%), and marble (3%).

Production was reported in 34 States and Puerto Rico. Leading producer States, in descending order by tonnage, were Indiana, Vermont, Wisconsin, Texas, and Georgia. These States accounted for 48% of the domestic production. The leading producer States, in descending order by value, were Indiana, Vermont, Minnesota, South Dakota, and North Carolina. These States contributed 49% of the value of domestic production (table 3).

The top five producing companies, listed alphabetically, were Buechel Stone Corp. in Wisconsin; Cold Spring Granite Co. in California, Minnesota, New York, Oklahoma, South Dakota, and Texas; Fletcher Granite Co., Inc., in Massachusetts and New Hampshire; Oolitic Victor Stone Co. in Indiana; and Rock of Ages Corp. in New Hampshire and Vermont. These companies produced about 27% of domestic production in tonnage and about 31% of production in value. The leading 14 companies accounted for 45% of total domestic tonnage and 47% of the value.

Granite.—Dimension granite was produced by 38 companies operating 70 quarries in 20 States. Production was 415,000 t valued at $112 million. Granite production tonnage decreased by 5% and value decreased by 3% compared with that of 1999. The top five producing States, in descending order by tonnage, were Massachusetts, Georgia, New Hampshire, South Dakota, and Idaho. Massachusetts accounted for 17% of the tonnage of U.S. granite production. Massachusetts and Georgia combined accounted for 23% of the value of the U.S. granite production (table 4).

The leading producers were Cold Spring Granite, Fletcher Granite, and Rock of Ages accounting for over one-half of U.S. granite production in tonnage and value.

Limestone.—Dimension limestone was produced by 30 companies from 34 quarries in 10 States. Production decreased by 3% to 432,000 t from 446,000 t in 1999, and the value decreased by 18% to $65.2 million from $79.1 million in 1999. The top five producing States, in descending order by tonnage, were Indiana, Wisconsin, Texas, Minnesota, and Kansas. Indiana produced 53% of the U.S. tonnage and 49% of the value (table 5).

The leading producers were Buechel Stone; Independent Limestone Co.; Indiana Limestone Co., Inc.; Oolitic Victor Stone; and Texas Stone Quarries. These firms accounted for 59% of total U.S. tonnage and about 42% of the value.

Sandstone.—Dimension sandstone was produced by 28 companies operating 33 quarries in 16 States. Production increased to 229,000 t in 2000 from 197,000 t in 1999. The value decreased by 12% to $22.9 million in 2000 from $25.9 million in 1999. The top five producing States, in descending order by tonnage, were New York, Arizona, Ohio, California, and Michigan. New York was the leading producing State with 25% of the tonnage and 19% of the value (table 6).

The leading producers were American Sandstone, Finger Lakes Stone Co. Inc., Waller Brothers Stone Co., Jude Stone Quarry Co., and Ulti-Solutions Inc. These companies accounted for about 67% of the tonnage and 58% of the value of domestic production.

Marble.—Marble was mined by six companies operating eight quarries in five States. Production declined to 31,300 t valued at $7.2 million from 38,300 t valued at $8.6 million in 1999 (table 10). Vermont was the leading producing State, followed by Georgia, Tennessee, Colorado, and Alabama. The leading producers were Vermont Quarries Co., Georgia Marble

Digitized by Google

Co., and Tennessee Marble Co. Additional data have been withheld to avoid disclosing company proprietary information.

Slate.—Slate was produced by 14 companies operating 20 quarries in 5 States. Production increased slightly to 28,700 t in 2000 from 28,600 t in 1999. The value increased by 1% to $14.2 million in 2000 from $14 million in 1999 (table 12). The producing States, in descending order by tonnage, were Vermont, Pennsylvania, New York, North Carolina, and California. The leading producers were U.S. Quarried Slate Products Inc., McAlpine Alfred Inc., Dally Slate Co., Ritchie Bros. Slate Co., and Quarry Slate Industries Inc. Additional data have been withheld to avoid disclosing company propriety information.

Consumption

Rough stone represented 55% of the tonnage and 46% of the value of all dimension stone sold or used by domestic producers, including exports. The largest uses of rough stone were in construction (50%) and irregular-shaped stone (19%) applications, by tonnage. Dressed stone represented 45% by tonnage and 54% by value of the total stone sold or used. The largest uses of dressed stone, by tonnage, were in flagging (28%), ashlars and partially squared pieces (20%), and curbing (10%) (table 7).

Uses for the different varieties of dimension stone varied considerably. The major uses of granite sold or used in 2000, by tonnage, were in rough blocks for construction (24%), monumental rough stone (21%), curbing (13%), monumental dressed stone (7%), and ashlars and partial squared pieces (6%) (table 8). Primary uses of limestone, by tonnage, were in rough blocks for building and construction (45%) and irregular-shaped stone (14%) (table 9). Primary uses of marble, by tonnage, were rough blocks for building and construction (44%) and dressed slabs and blocks for building and construction (13%) (table 10). Primary uses of sandstone, by tonnage, were in dressed stone for flagging (59%) and rough blocks for building and construction (12%) (table 11). Dimension slate sold or used by producers in the United States in 2000, by tonnage, was principally for roofing (38%), flooring (37%), and flagging (8%) (table 12).

Overall, the apparent consumption of dimension stone in the United States was estimated to be $1.1 billion in 2000, an increase of 8% compared with that of 1999. Apparent consumption is defined as production plus imports for consumption minus exports. Value data are used in the apparent consumption calculation because tonnage data are not available for imports and exports. Additionally, changes in industry stocks are not considered because the data are not available.

Prices

The average 2000 value for dimension stone was $188 per metric ton—a decrease of 7.8% from that of 1999, based on the USGS survey. The average unit values for different types of dimension stone were granite, $270 per ton; limestone, $151 per ton; sandstone, $100 per ton; marble, $228 per ton; and slate, $495 per ton. Price data that are available show considerable variation. Prices are substantially different not only for the kind of stone but also for the appearance of the same kind of stone. Color, grain structure, and finish contribute significantly to price and marketability.

Foreign Trade

Exports.—In 2000, total exports of dimension stone increased in value by about 9% to about $60 million compared with those of 1999; granite accounted for 58% of the export value. The largest share of granite was exported to China (table 13).

Imports.—The value of imports for consumption of dimension stone types increased in 2000 by about 14% to $925 million. Italy continued to be the major single source of granite, accounting for 42% of granite imports. Other important granite import sources included Brazil (18%), India (13%), and Canada (11%) (table 14). Italy also was a major source of rough and dressed marble, slate, and travertine imports (tables 15, 16). Duties on imported dimension stone are listed in table 2.

World Review

World dimension stone production, excluding the United States, was estimated to be approximately 60 Mt in 1999, and preliminary numbers indicated that this total was unchanged for 2000. Although some small-scale production probably occurred in the majority of the world's nations, dimension stone was produced and officially reported in about 34 countries. The top five producing countries in 1999, in descending order by tonnage, were China, Italy, India, Iran, and Spain. These countries accounted for about 72% of the world production. The United States ranked 10th in world production of dimension stone in 1999 (Internazionale Marmi e Macchine Carrara S.p.A., [2001], International quarry production, accessed August 27, 2001, at URL http://www.immcarrara.com/stat/english-version/index-stone-sector.html).

Outlook

The U.S. dimension stone industry has experienced renewed growth in the past 2 to 3 years, but the economic slowdown in late 2000 and early 2001 has reduced domestic production backlogs for most stone types. However, industry experts anticipate growth in dimension stone sales during the near term because of improved technology and variety and the increased costs of alternative construction materials. Additionally, for residential and office building construction, growth in the use of dimension stone is expected in new prestige markets for home improvement, as well as in renovations to attract and keep tenants.

STRONTIUM

By Joyce A. Ober

Domestic survey data and tables were prepared by Raymond I. Eldridge III, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Strontium occurs commonly in nature, averaging 0.034% of all igneous rock; only two minerals, celestite (strontium sulfate) and strontianite (strontium carbonate), however, contain strontium in sufficient quantities to make its recovery practical. Of the two, celestite occurs much more frequently in sedimentary deposits of sufficient enough size to make development of mining facilities attractive. Strontianite would be the more useful of the two common minerals because strontium is used most often in the carbonate form, but few deposits have been discovered that are suitable for development. A mine in China is believed to be the only developed strontianite deposit in the world (Hong, 1993).

Chemical Products Corp. (CPC) of Cartersville, GA, was the only U.S. producer of strontium compounds from celestite. CPC produced strontium carbonate from imported Mexican ore; no celestite mines were active in the United States.

Legislation and Government Programs

Government stockpiling of celestite began in 1942 to provide a secure supply for the production of strontium compounds required for defense applications during World War II. Celestite purchase specifications issued in 1960 for the national defense stockpile established quality requirements of greater than 95% strontium sulfate content with less than 1.5% calcium sulfate and less than 2% barium sulfate (U.S. Department of Defense, 1960).

In 1963, Congress determined that the celestite stockpile was unnecessary, and the General Services Administration began selling stockpiled material. All stockpile-grade celestite was sold by 1973. The remaining material graded less than 91% strontium sulfate and more than 4% calcium sulfate and some with more than 10% barium sulfate (Defense Logistics Agency, 1998).

In 2000, the stockpile contained approximately 12,000 metric tons (t) of celestite, all of which was authorized by Congress for disposal. The low quality of the material remaining in the stockpile made it undesirable as raw material for strontium carbonate production. Reports issued by the Defense National Stockpile Center of the Defense Logistics Agency, the agency now responsible for managing stockpile sales, listed the celestite as valueless.

Production

Although celestite mines have not been active in the United States since 1959, deposits have been identified nationwide. During World War II, celestite resources were mined in California and Texas; at that time, mines had been inactive since World War I, and strontium minerals were imported to satisfy

Strontium in the 20th Century

In 1900, no strontium minerals or chemicals were produced in the United States. Domestic production of celestite, a strontium sulfate ore, did not take place until 1916 when 250 metric tons containing approximately 100 tons of strontium were produced. Domestic and imported ores were used to produce strontium carbonate and strontium nitrate for use in fireworks, signal flares, refrigeration, steelmaking, and sugar beet processing. World War I created a demand for strontium nitrate for such military uses as tracer bullets and various types of flares. At the end of the war, demand decreased significantly. Domestic mining was inactive until the beginning of World War II, when military activities increased demand at the same time supply of imported ores from overseas was disrupted. Domestic production from California and Texas, with additional supplies from Mexico, were used to meet the demand with the few shipments that were available from the United Kingdom. During this time, celestite from Texas was used in drilling mud, substituting for barite, which was in short supply because of increased requirements for the war effort. The end of hostilities brought the collapse of the domestic celestite industry. The use of celestite in drilling muds ended at about the same time.

In the strontium chemical industry, domestic celestite could not compete in quality or price with imports from Mexico, Spain, and the United Kingdom. Domestic mining was minimal and sporadic until 1959 when it ceased completely. Uses for strontium chemicals for corrosion inhibitors, depilatories, greases, luminous paints, medicines, metallurgy, optics, and plastics increased slightly. In 1967, strontium ferrite ceramic magnets were developed. In 1969, strontium replaced barium in color television faceplate glass to block x-ray emissions, causing tremendous growth in the demand for strontium carbonate. By 1971, television glass was the largest end use for any strontium chemical and remained so through the end of the century, with its share of the strontium market increasing. Other uses were developed for strontium, but all were dwarfed by the chemical's consumption in television glass.

In 2000, U.S. apparent consumption was about 36,000 tons of contained strontium, about 77% of which was used in television glass and 10% in ferrite magnets. Pyrotechnic uses remained significant, accounting for an estimated 9% of total consumption. Other uses included the electrolytic production of zinc and applications in pigments and fillers.

Digitized by Google

domestic demand.

The sole U.S. strontium carbonate producer voluntarily provided domestic production and sales data to the U.S. Geological Survey (USGS). Production and stock data, however, have been withheld from publication to avoid disclosing company proprietary data (table 1). CPC was the only domestic company that produced strontium carbonate from celestite; the company also produced strontium nitrate. All the celestite CPC used in 2000 was imported from Mexico; CPC owned and operated a second strontium carbonate plant in Reynosa, Tamaulipas, Mexico. The company used the black ash method of strontium carbonate production at both of its facilities.

The black ash and the soda ash methods are the two most common recovery techniques. The black ash method, known alternatively as the calcining method, produces chemical-grade strontium carbonate, which contains at least 98% strontium carbonate. The soda ash or direct conversion method produces technical-grade strontium carbonate, containing at least 97% strontium carbonate.

The first step in the black ash process involves mixing the crushed and screened celestite with powdered coal. The mixture is then heated to about 1,100° C, expelling oxygen in the form of carbon dioxide from the insoluble strontium sulfate to form water-soluble strontium sulfide. Strontium sulfide is dissolved in water, and the resulting solution is filtered. Then either carbon dioxide is passed through the solution or soda ash is added, forming and precipitating strontium carbonate from the solution. The precipitated strontium carbonate is filtered, dried, ground, and packaged. The byproduct sulfur from the process is recovered as elemental sulfur or other byproduct sulfur compounds (Chemical Products Synopsis, 1993). The black ash method is the preferred means of strontium carbonate production because it yields a higher grade product; most new production facilities employ black ash technology.

In the soda ash method, ground celestite is washed and most of the water removed. The thickened mixture is combined with soda ash and treated with steam for 1 to 3 hours. During this time, celestite and soda ash react to form strontium carbonate and sodium sulfate. Sodium sulfate is water soluble, making it possible to separate the insoluble strontium carbonate by centrifuging.

Several U.S. companies produced strontium compounds from strontium carbonate. Mallinkrodt Chemical Inc. of St. Louis, MO, and Laporte Pigments Corp. of Beltsville, MD, produced strontium chloride and strontium chromate, respectively. A few other companies produced downstream strontium compounds on a limited scale.

Consumption

The USGS estimated the distribution of strontium compounds by end use. Of the six operations to which a survey request was sent, five responded. The information collected from this survey and the information provided by the U.S. Census Bureau on strontium trade were the bases for the end-use estimates listed in table 2.

In 2000, more than 85% of all strontium was consumed in ceramics and glass manufacture, primarily in television faceplate glass and secondarily in ceramic ferrite magnets and other ceramic and glass applications. Since 1970, production of faceplate glass for color television picture tubes had been the major use of strontium.

All color televisions and other devices containing color cathode-ray tubes (CRTs) sold in the United States were required by law to contain strontium in the faceplate glass of the picture tube to block x-ray emissions. Major manufacturers of television picture tube glass incorporated, by weight, about 8% strontium oxide in their glass faceplate material. Added to the glass melt in the form of strontium carbonate, it was converted to strontium oxide. In addition to blocking x rays, strontium improves the appearance of the glass and the quality of the picture and increases the brilliance (Wagner, 1986).

Permanent ceramic magnets were another large end use for strontium compounds in the form of strontium ferrite. These magnets were used extensively in small direct current motors for automobile windshield wipers, loudspeakers, other electronic equipment, toys, and magnetically attached decorative items. Strontium ferrite magnets have high coercive force and high thermal and electrical resistivities and are chemically inert. They retain their magnetism well, are not adversely affected by electrical currents or high temperatures, do not react with most chemical solvents, and have a low density (Haberberger, 1971).

One of the most consistent and continuing applications for strontium was in pyrotechnic devices. Strontium burns with a brilliant red flame, and no other material was known to be better in this application. The compound used most frequently in these devices was strontium nitrate. Although strontium carbonate, strontium oxalate, strontium sulfate, and strontium chlorate could also be used, strontium nitrate was used in significantly larger quantities. Pyrotechnic devices were used in military and nonmilitary applications. Military pyrotechnic applications included tracer ammunition, military flares, and marine distress signals. Nonmilitary applications included warning devices and fireworks (Conkling, 1981).

Strontium can be used to remove lead impurities during the electrolytic production of zinc. The addition of strontium carbonate dissolved in sulfuric acid to the electrolyte reduces the lead content of the electrolyte and of the zinc deposited on the cathode (Bratt and Smith, 1963).

Strontium chromate also was used as an additive to corrosion-resistant paint to effectively coat aluminum most notably on aircraft fuselages and ships. These paints were used, to some degree, on aluminum packaging to prevent corrosion (Roskill Information Services Ltd., 1992, p. 76).

Strontium metal had a very limited part in total strontium consumption. Small amounts of strontium added to molten aluminum improve the castability of the metal, making it more suitable for casting items that had been made traditionally from steel. The addition of strontium to the melt improved the machinability of the casting. The use of cast aluminum parts had become common in the automotive industry because of the reduced weight and improved gas mileage achieved from the use of cast aluminum parts instead of steel (Lidman, 1984).

Other end uses consumed only small amounts of strontium and strontium compounds. As mentioned above, the presence of strontium in glass applications improves the brilliance of the glass. It also improves the quality of certain ceramic glazes, and eliminates the toxicity that may be present in glazes containing lead or barium. Strontium titanate was sometimes used as substrate material for semiconductors and in some optical and piezoelectric applications. Strontium chloride was used in toothpaste for temperature-sensitive teeth. For this application,

Digitized by Google

impurities must be strictly controlled; some limits are in the parts-per-million range. Strontium phosphate was used in the manufacture of fluorescent lights, and the entire range of strontium chemicals was used in analytical chemistry laboratories.

Prices

Based on data published by the U.S. Census Bureau, the average customs value for celestite imported from Mexico was about $63 per ton, 12.5% lower than that of 1999. The average unit customs value of imported strontium carbonate was $0.56 per kilogram, slightly lower than in 1999. The corresponding value for strontium nitrate was $3.53 per kilogram, a decrease of about 9% from that of 1999.

Foreign Trade

Exports of strontium compounds were 52% higher than the levels reported in 1999 (table 3). This increase in exports was a result of increased strontium carbonate exports to Asia. In 1998, U.S. strontium carbonate exports to Asian countries were 24 t; in 1999 exports to Japan, Singapore, Taiwan, and Thailand totaled 3,500 t. The growth continued in 2000, with exports to Japan, the Republic of Korea, Singapore, and Taiwan totaling 5,680 t. This astounding increase was due to decreased production in Japan that resulted from plant closures in 1998 and high demand for strontium carbonate at television glass operations in Asia.

Imports of celestite from Mexico were 17,000 t, a decrease of nearly 46% from those of 1999. Although celestite import figures have varied significantly from year to year, the decease appeared to be attributable to a 2-year cycle of celestite imports. During the past 5 years, annual celestite imports averaged about 27,300 t (12,000 t contained strontium).

Mexico continued to be the most important source for imported strontium compounds, followed by Germany (table 4). Imports of strontium carbonate in 2000 were 12% higher than those of 1999. Imports from Mexico were 94% of total carbonate imports. Imports of strontium nitrate were 16% higher than those of 1999. Strontium nitrate imports have varied significantly from one year to the next but represented only about 1% of total strontium imports.

World Review

In most instances, celestite deposits occur in remote, undeveloped locations far from population centers in areas where inexpensive labor is available for mining. Huge deposits of high-grade celestite have been discovered throughout the world. Strontium commonly occurs along with barium and calcium, two elements with chemical properties very similar to strontium, thus making separation difficult. Because removing many impurities from celestite is difficult and energy-intensive, strontium chemical producers require that material contain at least 90% strontium sulfate. Most operating celestite facilities can produce sufficient supplies with only minimal processing necessary to achieve acceptable specifications. Hand sorting and some washing are all that are necessary at many strontium mines; a few operations use gravity separation, froth flotation, or other methods to beneficiate ore.

The leading celestite producing countries were, in decreasing order of importance, Mexico, Spain, and Turkey. Significant quantities of celestite were produced in China and the former Soviet Union (FSU); not enough information was available, however, to make any estimates on location, number, or size of mines. Celestite was produced in smaller quantities in Argentina, Iran, and Pakistan.

Detailed information on most world resources was not readily available because very little information on exploration results had been published. Other deposits may well be identified but are in countries from which specific minerals information is not easily obtained (table 5). Production facilities for strontium compounds and metal were located in Canada, China, the FSU, Germany, Japan, the Republic of Korea, Mexico, Poland, and the United States.

Canada.—The world's leading producer of strontium metal, Timminco Ltd. produces strontium metal in Ontario. The company also produces strontium-aluminum master alloys, which were advertised as the highest quality in the world, referring to their purity, low gas content, fast dissolution rate, low porosity, precise weight, and highest and most consistent strontium recovery. Timminco sells strontium as crowns, sections, and turnings and in master alloys containing 90% strontium and 10% aluminum (Timminco Ltd., [undated], Strontium products, accessed May 25, 2001, at URL http://www.timminco.com/products/strontium.html).

Germany.—Solvay Barium Strontium GmbH, a subsidiary of Belgium's Solvay S.A., operates a 150,000-ton-per-year (t/yr) barium and strontium carbonate plant at Bad Hönningen. Solvay used imported Spanish celestite as the raw material for strontium carbonate production. The company has other strontium carbonate plants in Italy, the Republic of Korea, and Mexico (Industrial Minerals, 1999b).

Mexico.—With three strontium carbonate plants operated by CPC, Cia. Minera La Valenciana S.A. de C.V. (CMV), and Solvay Química y Minera, S.A. de C.V., Mexico was the world's largest producer of strontium carbonate. The vast majority of all U.S. strontium imports came from Mexico. CPC met its celestite requirements for its plants in Georgia and Mexico from mines that were completely controlled by CPC (Chemical Products Corp., [undated], Profile of Chemical Products Corporation, accessed May 25, 2001, at URL http://www.ceramics.com/cpc/cpc.html). CMV had proven and estimated reserves of 5 million metric tons, enough to continue production well into the future (Cia. Minera La Valenciana S.A. de C.V., [undated], Our future and our plans to remain the best, accessed May 25, 2001, at URL http://www.cmvlavalenciana.com.mx/our_future_and_plans_to_remain_the_best.htm).

Spain.—Two companies operated celestite mines in Spain, the last remaining celestite producing country in Europe. Solvay mined the Escuzar deposit to supply its German strontium carbonate operation. Canteras Industriales SL, a subsidiary of Bruno S.A., produced celestite from the Montevives deposit. Quimico Estroncio, a joint venture of Minas de Almadadén y Arrayanes, S.A., Fertiberia S.A., and Erkimia S.A., completed a new 22,000-t/yr strontium carbonate plant in Cartegena early in the year. The plant will produce strontium carbonate from Spanish celestite (Reguiro y Gonzáles-Barros and Sanz, 2000, p. 53-55). No production details from the new plant were available.

Turkey.—A long-time celestite producer for the export market, Barit Maden Turk AS sold most of its production to the

Digitized by Google

Republic of Korea and China. The company was building its own strontium carbonate plant in 2000. In preparation for its expansion into carbonate production, Barit Maden built a carbon dioxide plant that was profitable for the company even before the strontium carbonate facilities were complete. Its high-quality celestite resources and the in-house carbon dioxide supply contributed to Barit Maden's confidence that its strontium carbonate would be high-quality and cost-competitive with other producers (Houssa, 1999, p. 47).

Outlook

Sales of televisions and computer monitors in the United States will continue at a high rate and will continue to influence U.S. strontium consumption significantly. Consumption for glass and ceramic applications for strontium carbonate is expected to grow at 3% to 5% per year for the near future (Industrial Minerals, 1999a). As long as CRTs are the preferred display type for televisions and computers, trends should remain steady with some small increases. Growth in television sales is expected to continue, and larger screens are increasing in popularity. Likewise, the market for personal computers is expanding, and the average size of monitors is increasing. These factors are driving increased demand for strontium carbonate for CRTs. Ferrite magnet markets are expected to be strong. Growth in other markets will probably continue at the current slower rate. Improved economic conditions worldwide will spur growth in demand for strontium carbonate.

Flat screen display systems for televisions and computer monitors have threatened to replace CRTs for many years, but low-cost technology has been elusive. Improvements have increased the likelihood that the large flat screens using either liquid crystal displays (LCDs) or plasma technology will replace bulkier CRTs. LCDs, which are smaller and use less energy than plasma display systems, seem to be filling the market for relatively small flat displays such as those required for portable computers. This market has experienced remarkable growth since 1997, and this trend is expected to continue. Plasma technology is more common for large, high-definition televisions with screens up to 60 inches wide. Significant growth is expected also in this area (Tremblay, 1999). Neither of these developing technologies requires strontium carbonate in the glass, but both are currently too expensive to make serious inroads in the domestic CRT market. The first common applications of flat screens should occur in Japan, where many homes are small and space is at a premium. A 20-inch flat screen television in Japan can cost around $2,500, significantly more than a comparable device with a CRT. Larger plasma screens (usually between 37 and 60 inches diagonally) cost between $10,000 and $14,000 (Landers, 2000).

Most of these devices were only available in Japan in 2000 but will eventually find acceptance in the United States, especially as the technology matures and prices go down. When these new display systems become more economically attractive to the general public, CRTs will become obsolete and so will the major market for strontium carbonate.

SULFUR

By Joyce A. Ober

Domestic survey data and tables were prepared by Maria Arguelles, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

After nearly a century of world dominance in the production of native sulfur, the U.S. Frasch industry shuttered its last mine as a result of low sulfur prices, which were caused by weakened demand for phosphate processing, continually increasing competition from low-cost recovered sulfur producers, escalating production costs, and technical problems. Worldwide, production of native sulfur and pyrites continued to decline as environmental regulations forced increased sulfur recovery to limit atmospheric emissions of sulfur dioxide. Growth in sulfur recovery continued to outpace sulfur demand, resulting in increased stocks worldwide.

Through its major derivative, sulfuric acid, sulfur ranks as one of the more important elements used as an industrial raw material. It is of prime importance to every sector of the world's industrial and fertilizer complexes. Sulfuric acid production is the major end use for sulfur, and consumption of sulfuric acid has been regarded as one of the best indices of a nation's industrial development. More sulfuric acid is produced in the United States every year than any other chemical; 39.9 million metric tons (Mt), equivalent to about 13.1 Mt of elemental sulfur, were produced in 2000, slightly less than that in 1999 (U.S. Census Bureau, 2001).

Domestic production of sulfur in all forms was 9% lower; shipments, consumption, imports, and prices decreased (table 1; figures 1, 2). The United States maintained its position as the leading world producer and consumer of sulfur and sulfuric acid. The quantity of sulfur recovered during the refining of petroleum and the processing of natural gas continued the upward trend established in 1939. Sulfur produced by using the Frasch process was 50% lower than that of 1999 because of the closure of the last mine. Frasch production data were estimated by the U.S. Geological Survey (USGS) based on company reports and other public information. Production of recovered sulfur from petroleum refineries and natural gas processing operations was slightly higher than in 1999, although production from petroleum refining increased and natural-gas recovery remained about the same. Because shipments were higher than production, stocks decreased by 54%.

Byproduct sulfuric acid from the Nation's nonferrous smelters and roasters, produced as a result of laws restricting sulfur dioxide emissions, supplied a significant quantity of sulfuric acid to the domestic merchant (commercial) acid market. Production from this sector decreased by 22% because the three copper smelters that closed in 1999 were not reopened.

World sulfur production changed little in 2000 (table 1). Frasch production was lower because of continued production cutbacks in the United States. Elemental sulfur production from recovered sources, primarily during the processing of natural gas and petroleum products, increased slightly. Approximately 86% of the world's elemental sulfur production came from recovered sources; the quantity of sulfur supplied from these sources was dependent on the world demand for fuels, nonferrous metals, and petroleum products, not for sulfur.

World sulfur consumption remained about the same with

Sulfur in the 20th Century

In 1900, Herman Frasch was trying to perfect his hot water melting process for producing sulfur. Domestic production was about 3,200 metric tons of sulfur valued at $88,100. Native sulfur deposits in Louisiana, Nevada, Texas, and Utah were mined with conventional mining methods. Domestic sulfur production, including mined elemental sulfur and pyrites, supplied about one-quarter of the U.S. sulfur demand of about 415,000 tons. Most sulfur and pyrites, domestic and imported, were used to produce sulfuric acid that was consumed in many different industries. Virtually all elemental sulfur imports came from the Italian island of Sicily, and pyrite imports were from unspecified locations. Pyrites remained a significant raw material for sulfuric acid until 1982. When the Frasch process was successfully commercialized in 1903, the U.S. sulfur industry took a turn for the better. By about 1915, the United States surpassed Italy as the world's leading producer of sulfur, a situation that continued throughout the century, during which eight companies produced nearly 340 million tons of sulfur from 36 mines in Louisiana and Texas. Frasch sulfur production hit its peak in 1974 when 12 mines produced 8 million tons.

Domestic production of elemental sulfur recovered as a byproduct of natural gas processing and oil refining was first reported in 1938 and grew steadily from that time. Recovered sulfur overtook Frasch as the primary domestic sulfur source in 1982. Sulfur also was recovered in the form of byproduct sulfuric acid from nonferrous metal smelters; production data were published for the first time in 1911.

In 2000, domestic sulfur production totaled 10.3 million tons, 81% from recovered operations, 9% from one Frasch mine, and 10% as byproduct acid from nonferrous metal smelters. Consumption was 12.5 million tons, including 2.8 million tons of imported sulfur and sulfur contained in sulfuric acid. The end uses did not change significantly during the century, although consumption in 2000 was nearly 4,000 times higher than it was in 1900. About 90% of domestic sulfur consumption was converted to sulfuric acid and then used, in decreasing order, in phosphate fertilizer and other agricultural chemical production, in oil refining, in copper ore leaching, and in many other industrial uses. Elemental sulfur was used as a plant nutrient, in synthetic rubber production, in pulp and paper products, and in other inorganic chemicals.

Digitized by Google

about 50% used in fertilizer production and the remainder in myriad other industrial uses. World trade of elemental sulfur increased slightly from the levels recorded in 1999. Worldwide inventories of elemental sulfur were higher.

Legislation and Government Programs

The U.S. Environmental Protection Agency (EPA) issued the final rule for reduced sulfur content of gasoline early in 2000, as part of tier 2 of the Clean Air Act Amendments of 1990. The standards were nationwide standards, with the implementation time extended for some States and for some refining facilities. By 2006, the sulfur content in gasoline must average 30 parts per million (ppm) with an upper limit of 80 ppm. States in the Rocky Mountain region and Alaska were given until 2007 to reach standards, because those States generally had better air quality than other parts of the country. Small refineries with fewer than 1,500 employees or less than 155,000 barrels per day (bbl/d) of processing capacity were required to meet interim goals until 2008, when the national limits would be imposed. The 2008 deadline could be delayed until 2010 if the refiners could demonstrate a severe economic hardship. Small refineries received special consideration because the installation of new equipment in small facilities could be economically damaging (Oil & Gas Journal, 2000b).

The EPA began the process for new sulfur standards for diesel fuel by proposing new limits for sulfur, reducing the allowable content from 500 ppm to 15 ppm, a 97% decrease. The final rule was announced in December, although implementation of the new rule was delayed for further review. The EPA reduced diesel sulfur levels in a first step to clean up emissions from heavy-duty trucks and buses. In addition to reducing sulfur dioxide emissions from diesel engines, changes were made because new emission control apparatus needed to reduce particulate emissions from these vehicles could not operate effectively unless sulfur levels in the fuel were significantly reduced. The agency estimated the cost of diesel regulations at 4 to 5 cents per gallon (Oil & Gas Journal, 2001).

The petroleum refining industry was concerned, however, that the cost of compliance might be significantly higher than the EPA estimated, in the range of 15 to 50 cents per gallon. Costs that high could make it economically unfeasible for some facilities to install the necessary apparatus, forcing closure of refining capacity, and perhaps causing shortages in supply (Chemical Market Reporter, 2001). Low-sulfur diesel presented more technological challenges than low-sulfur gasoline, requiring more substantial investments for high-pressure hydrotreating facilities. The sulfur compounds found in diesel are more difficult to remove than those found in gasoline (Moyse, 2000). Refineries had several options for reducing sulfur levels to meet new regulations. The least expensive choice was using advanced catalysts in desulfurization units. Not all refineries would be able to use this alternative (Garritsen and others, 2000). Other more expensive treatment options for producing low-sulfur fuels were known (Moyse, 2000).

Other concerns about the new regulations addressed the issues of timing and transportation. Implementation of the new regulations was required on approximately the same time frame as those for gasoline. Questions were raised as to whether the refining industry would be able to make the required upgrades to diesel and gasoline facilities simultaneously without compromising the availability of either product. In addition, most diesel fuel is transported via pipelines that also transport home heating oil for which no new sulfur requirements were enacted. Industry officials believed that it would be difficult to prevent diesel product contamination from the pipelines that also carried the higher sulfur heating oil (Hess, 2000).

Production

Elemental Sulfur.—Production statistics were collected on a monthly basis and published in the USGS monthly sulfur Mineral Industry Surveys. All of the 120 operations to which survey requests were sent responded, representing 100% of the total production shown in table 1. In 2000, production was 7% lower than that of 1999. Shipments decreased by 3%, and the value of shipments was 35% lower owing to a decrease in the average unit value of elemental sulfur. Trends in sulfur production are shown in figure 2.

Frasch.—Native sulfur associated with the caprock of salt domes and in sedimentary deposits was mined by the Frasch hot-water method, in which the native sulfur was melted underground and brought to the surface by compressed air. Freeport-McMoRan Sulphur Inc., a subsidiary of McMoRan Exploration Co., was the last remaining Frasch producer in the United States. After announcing plans in July to close its Main Pass Mine by the end of the year, Freeport abruptly closed the mine 4 months early, at the end of August, citing low sulfur prices and increased operating expenses, especially natural gas prices, for the early closure (Fertilizer Markets, 2000c). An example of the scope of increased costs was the price of natural gas, a major constituent of Frasch production cost, which nearly doubled from the beginning of the year to July, with additional increases set for September (McMoRan Exploration Co., 2000b).

The mine also was closed ahead of schedule because a geologic and tectonic study revealed significant stability problems in a subsurface brine cavity. Continued production would have been impossible without substantial investment to remediate the problem. Because drilling activities had already been curtailed and mining was to be suspended at the end of the year, the company decided to close the mine rather than to incur the expense necessary alleviate the technical problems (Green Markets, 2000).

Main Pass was a mine operated on a salt dome sulfur deposit in the Gulf of Mexico, about 51 kilometers (km) (32 miles) from the coast of Louisiana. The Main Pass offshore complex, which was more than 1.6 km (1 mile) long and was the largest structure in the Gulf, had a production capacity of more than 5,500 metric tons per day (t/d) (McMoRan Exploration Co., 2000a). Production began in 1991 at a development cost of $880 million (Chemical & Engineering News, 2000).

When Freeport announced plans to close its mine, it proposed to concentrate on its sulfur transportation and marketing business and to continue meeting its supply contracts through purchases of recovered sulfur. The company later offered the sulfur logistics business for sale, expecting about $80 million for the deal. By yearend, a buyer had not been identified (Fertilizer Markets, 2001). In addition to the mine, Freeport's operations included facilities for forming, loading, remelting, and transporting sulfur in Galveston, TX; Port Sulphur, LA; and Tampa, FL.

Recovered.—Recovered elemental sulfur, a nondiscretionary byproduct from petroleum refining, natural gas processing, and

Digitized by Google

coking plants, was produced primarily to comply with environmental regulations that were applicable directly to emissions from the processing facility or indirectly by restricting the sulfur content of the fuels sold or used by the facility. Recovered sulfur was produced by 39 companies at 117 plants in 26 States and 1 plant in the U.S. Virgin Islands. Most of these plants were small, with 33 reporting production exceeding 100,000 metric tons per year (t/yr). By source, 76% of recovered elemental sulfur production came from petroleum refineries or satellite plants treating refinery gases and coking plants. The remainder was produced at natural gas treatment plants. The largest recovered sulfur producers, in descending order of production, were Exxon Mobil Corp. (ExxonMobil), BP p.l.c., Chevron Corp., and Motiva Enterprises LLC. The 35 plants owned by these companies accounted for 50% of recovered sulfur output during the year. Recovered sulfur production by State and region is listed in tables 2 and 3.

Five of the 15 largest refineries in the world are in the United States. They are, listed by declining refining capacity, Hovensa LLC's St. Croix, U.S. Virgin Islands, refinery; ExxonMobil's Baytown, TX, and Baton Rouge, LA, refineries; and BP's Texas City, TX, and Whiting, IN, refineries (Chang, Thi, 2000), all of which were significant sulfur producing facilities. Refining capacity does not necessarily mean that these refineries are the largest producers of refinery sulfur. Sulfur production depends on installed sulfur recovery capacity, as well as the types of crude that are refined at the specific refineries. Large refineries that process low-sulfur crudes may have relatively low sulfur production.

Consolidation in the petroleum industry reduced the number of companies operating sulfur recovery operations, although the number of sulfur plants remained about the same. In 1998, Amoco Co. and British Petroleum Co., p.l.c., merged to form BP Amoco p.l.c. (BP Amoco p.l.c., 1999). On November 30, 1999, the U.S. Federal Trade Commission (FTC) approved the merger of Exxon Corp. and Mobil Corp. to form ExxonMobil (Chang, Joseph, 1999).

In April, the FTC approved the merger of BP Amoco p.l.c. with Atlantic Richfield Co. (ARCO). In order to receive approval, the companies agreed to sell all of ARCO's Alaska operations to Phillips Petroleum Co. The new company was called BP Amoco ARCO p.l.c., but the name was quickly simplified to BP p.l.c. (Oil & Gas Journal, 2000a).

Chevron Corp. and Texaco Inc. announced plans to merge to form ChevronTexaco Corp. The companies planned to merge in order to be better able to develop new oilfields and sources of energy (Hoffman, 2000). The new company will be the third largest oil and gas producer in the United States after ExxonMobil and BP. Some divestitures were likely to be required by the FTC before approval. Of particular interest were Texaco's refining and marketing joint ventures with Shell Oil Co. and Saudi Arabian Oil Co. (Westervelt, 2000). In response to the proposed merger of Chevron and Texaco, Shell considered buying Texaco's share of the Shell/Texaco alliances formed in 1997. This arrangement could eliminate many of the regulatory hurdles the Chevron/Texaco merger faced (PentaSul North America Sulphur Review, 2000a).

Mergers were becoming more common in the natural gas industry also. Duke Energy Corp. merged with Phillips Petroleum's gas gathering, processing, and marketing unit to form Duke Energy Field Services, LLC, owned 70% by Duke Energy and 30% by Phillips Petroleum (Duke Energy Corp., 2001, p. 12). El Paso Energy Corp. was in the process of acquiring The Coastal Corp. (North America Sulphur Service, 2000a). The El Paso Energy/Coastal merger was completed early in 2001, and the name was changed to El Paso Corp. (El Paso Energy Corp., 2001; El Paso Corp., 2001).

Several refining companies were in the process of upgrading their facilities to produce low sulfur fuels from higher sulfur crude oil. ExxonMobil was building a 40,000 bbl/d coker at its Baytown, TX, refinery in order to handle 530,000 bbl/d of Mexican sour crude from Petróleos Mexicano S.A. de C.V. (Pemex). The upgrades were designed to increase the quality of the fuels produced at Baytown. Sulfur production at the plant was likely to increase to between 350,000 to 360,000 t/yr from about 300,000 t/yr (North American Sulphur Service, 2000c). Marathon Ashland Petroleum LLC was upgrading and adding sulfur recovery capacity at its Garyville, LA, refineries to handle imports from Pemex (Cunningham, 1999b). The Premcor Refining Group Inc.—formerly Clark Refining & Marketing, Inc.—was upgrading its Port Arthur, TX, refinery to handle more heavy crude. New sulfur recovery capacity was being installed to increase production to more than 200,000 t/yr from 130,000 t/yr (North America Sulphur Service, 2000e).

Other companies were involved in joint ventures in which foreign sour crude producers contributed financing for the upgraded facilities. Phillips Petroleum and Petróleos de Venezuela, S.A. (PdVSA), completed installation of a new vacuum distillation unit and a coker at the Phillips Sweeny, TX, refinery to enable the facility to handle heavy crudes like those produced by PdVSA from the Venezuelan Orinoco Basin (Oil & Gas Journal, 2000c). Shell Oil Co. and Pemex were expanding their joint-venture Deer Park, TX, refinery to 340,000 bbl/d from 280,000 bbl/d. Maya crude will make up 65% of the throughput. Additional sulfur recovery capacity was to bring sulfur capacity to about 200,000 t/yr (North America Sulphur Service, 1999a).

Byproduct Sulfuric Acid.—Sulfuric acid production at copper, lead, molybdenum, and zinc roasters and smelters (table 4) accounted for about 10% of the total domestic production of sulfur in all forms, down from 12% in 1999. Four acid plants operated in conjunction with copper smelters, and six were accessories to lead, molybdenum, and zinc smelting and roasting operations. Even with the cutbacks at copper smelters, the four largest acid plants were all associated with copper mines and accounted for 81% of the output. The largest producers—ASARCO Incorprated, Kennecott Utah Copper Corp., and Phelps Dodge Corp.—operated a total of four copper smelters.

Byproduct acid decreased by 22% from that of 1999, because three of the seven copper smelters in the United States remained closed during the year. The 1999 closures resulted from a serious slump in the world copper industry, with adjusted copper prices lower than they had been at any time in the 20th century (McCoy, 1999).

Consumption

Apparent domestic consumption of sulfur in all forms was 7.0% lower than that of 1999 (table 5). Of the sulfur consumed, 77.6% was obtained from domestic sources, such as elemental sulfur (69.9%) and byproduct acid (7.7%), compared with 77.4% in 1999 and 79.2% in 1998. The remaining 22.4% was supplied by imports of recovered elemental sulfur (18.7%) and

Digitized by Google

sulfuric acid (3.7%). The USGS collected end-use data on sulfur and sulfuric acid according to the standard industrial classification of industrial activities (tables 6, 7).

Sulfur differs from most other major mineral commodities in that its primary use is as a chemical reagent rather than as a component of a finished product. This use generally requires that it be converted to an intermediate chemical product prior to its initial use by industry. The largest sulfur end use, sulfuric acid, represented 77% of reported consumption with an identified end use. Some identified sulfur end uses were tabulated in the "Unidentified" category because these data were proprietary. Data collected from companies that did not identify shipment by end use also were tabulated as "Unidentified." A significant portion of the sulfur in the "Unidentified" category may have been shipped to sulfuric acid producers or exported, although data to support such an assumption were not available.

Because of its desirable properties, sulfuric acid retained its position as the most universally used mineral acid and the most produced and consumed inorganic chemical, by volume. Based on USGS surveys, reported U.S. consumption of sulfur in sulfuric acid (100% basis) decreased by 7.5% and total sulfur consumption was 4.9% lower than that of 1999.

Agriculture was the largest sulfur-consuming industry, although it decreased to 8.6 Mt compared with 9.2 Mt in 1999. Reported consumption in phosphatic fertilizers was 8.5% lower than that of 1999, a result of decreased production of phosphoric acid. Based on export data from the U.S. Census Bureau, the estimated quantity of sulfur needed to manufacture exported phosphatic fertilizers increased by 16% to 4.8 Mt.

The second largest end use for sulfur was in petroleum refining and other petroleum and coal products. Producers of sulfur and sulfuric acid reported a slight increase in the consumption of sulfur in that end use. Because oil refineries had operated near capacity in 1999 and 2000, little change was expected.

Demand for sulfuric acid in copper ore leaching, the third largest end use, decreased by 7.6%. This use of sulfuric acid decreased for the second consecutive year as a result of downturns in the copper industry. Planned expansions at copper leach operations, however, were expected to cause increased consumption for this use by 2001. All copper producers, even companies that closed smelter operations, continued to operate their solvent extraction-electrowinning (SX-EW) operations in which weak sulfuric acid dissolves copper as it percolates through specially prepared beds of copper minerals. The copper is then concentrated through a solvent extraction process, and the concentrated solution undergoes an electrowinning process that produces 99.99% copper cathode (Phelps Dodge Corp., 1999).

Phelps Dodge was converting its Morenci, AZ, site to the SX-EW process. Upon completion, the 45% increase in SX-EW capacity should require a comparable increase in sulfuric acid consumption for the process. The company's copper smelter near Chino, NM, initially was expected to supply a portion of the necessary acid with the remainder being purchased (Sulfuric Acid Today, 1999). The decreased byproduct acid production resulting from the closed smelters and the expansion of solvent extraction operations in the same area presented the potential for reduced acid supplies for the new SX-EW capacity. Phelps Dodge was considering the option of installing a sulfur burner at its shuttered Hidalgo, NM, sulfuric acid plant. The company would be able to meet its requirements for its leach operations with virgin acid from Hidalgo (North America Sulphur Service, 2000b). Poorer than expected financial results for the company in the first half of 2000 delayed action on the sulfur burner plan (North America Sulphur Service, 2000d). A new solvent extraction copper operation was planned for development in Utah that would use byproduct sulfuric acid produced at Kennecott Utah Copper's smelter (Sulphur, 2000a).

The U.S. Census Bureau reported 5.73 Mt of sulfuric acid was produced as a result of recycling spent and contaminated acid from petroleum alkylation and other processes (U.S. Census Bureau, 2001). This material was recycled by companies that produced acid for consumption in their own operations and also recycled acid used in their plants. The petroleum refining industry was believed to be the largest source and consumer of recycled acid for use in its alkylation process.

Stocks

Yearend inventories held by Frasch and recovered elemental sulfur producers decreased to 208,000 metric tons (t), about 54% less than those of 1999 (table 1). Based on apparent consumption of all forms of sulfur, combined yearend stocks amounted to about a 6-day supply, compared with a 12-day supply in 1999, a 7-day supply in 1998, a 20-day supply in 1997, and a 17-day supply in 1996. Yearend stocks were lower than they had been since Frasch production became profitable early in the 20th century (Haynes, 1959, p. 61). Final stocks represent 4% of the quantity held in inventories at the end of 1976, when sulfur stocks peaked at 5.65 Mt, a 7.4-month supply at that time (Shelton, 1978, p. 1296). In October, Freeport shipped nearly all the sulfur it had in stocks as it was attempting to exit the sulfur business. In most cases, it was difficult for recovered sulfur producers to accumulate any significant stockpiles. Many recovered operations did not have sufficient space for storing excess sulfur, and in many locations, environmental regulations did not allow stockpiling to occur. Without Frasch production, domestic sulfur stocks were expected to remain relatively stable.

Prices

The contract prices for elemental sulfur, at terminals in Tampa, FL, reported weekly in Green Markets, began the year at $61 to $64 per metric ton. Prices quickly decreased to between $56 to $59 per ton and remained steady until the end of October, when they increased to between $62 to $66 per ton, where they remained throughout the rest of the year.

Based on total shipments and value reported to the USGS, the average value of shipments for all elemental sulfur was $24.73 per ton, which was 35% lower than that of 1999. Prices varied greatly on a regional basis, causing the discrepancies between Green Markets prices and USGS prices. Tampa prices were usually the highest prices reported because of the large sulfur demand in the central Florida area. U.S. West Coast prices were $0 to $1 per ton, though, in reality, West Coast producers often faced negative values as a result of costs incurred at forming plants. These costs were necessary to make solid sulfur in acceptable forms, often known as prills, to be shipped overseas. The majority of West Coast sulfur was sent to prillers

Digitized by Google

who may have been subsidized by the refineries, and the formed sulfur was shipped overseas (Green Markets, 1999c).

Foreign Trade

Exports of elemental sulfur from the United States, including the U.S. Virgin Islands, were 11% higher in quantity than those of 1999 and 50% higher in value, as listed in table 8, because the average unit value of U.S. export material increased. The average unit value of exported elemental sulfur increased to $70 per ton from $52 per ton, which was 35% higher than in 1999. Exports from the West Coast were 659,000 t, or 86% of total U.S. exports.

The United States continued to be a net importer of sulfur—imports of elemental sulfur exceeded exports by 1.6 Mt. Recovered elemental sulfur from Canada and Mexico delivered to U.S. terminals and consumers in the liquid phase furnished about 94% of all U.S. sulfur import requirements. Total elemental sulfur imports decreased by about 10% in quantity and decreased by 24% in value; imports from Canada, mostly by rail, were 3% higher; and waterborne shipments from Mexico were 10% lower than those of 1999 (table 10). Imports from Venezuela were estimated to account for about 6% of all imported sulfur.

The most unusual detail concerning imports was that one shipment of about 46,000 t of formed Canadian sulfur was transported by ship from Vancouver, British Colombia, to Galveston, TX. Because the closure of Main Pass raised questions about possible sulfur supply shortages by yearend, Freeport imported one shipload of solid sulfur from Canada. Unlike most Canadian imports that entered the United States as molten sulfur by rail into the northern States and went cross-country to Florida, Freeport's shipment was transported by ship from Vancouver to Galveston, where Freeport operated remelting facilities. Freeport also bought formed sulfur from Hovensa LLC in St. Croix, U.S. Virgin Islands, for remelting to meet their supply contracts (PentaSul North America Sulphur Review, 2000b).

With the decreased supplies and some concern of price increases at yearend, several Florida fertilizer companies were pursuing necessary permits to build a terminal south of Tampa to handle formed sulfur. After several unexpected delays late in 2000, Big Bend Transfer Station Co. (BBTC) received from the Hillsborough County Commission approval for its sulfur melting plant south of Tampa early in 2001. The joint venture formed by Cargill Inc.; CF Industries, Inc.; and IMC Global Inc. planned to build a facility for remelting formed sulfur as a means of diversifying their supply options. The project needed an air quality permit from the county's Environmental Protection Commission. Upon successful completion of the permitting process, BBTC planned to install facilities for handling 1.5 million tons per year (Mt/yr) of sulfur, with possible expansions to 2 Mt/yr (Green Markets, 2001). This would enable BBTC to buy formed sulfur at the best prices available, perhaps from foreign producers.

In addition to elemental sulfur, the United States also had significant trade in sulfuric acid. Sulfuric acid exports were 23% higher than those of 1999 (table 9). Acid imports were more than seven times greater than exports (tables 9, 11). Canada was the source of 57% of U.S. acid imports, most of which were probably byproduct acid from smelters. Canadian shipments to the United States came by rail, and the remainder of imports came primarily by ship from Europe, Latin America, and Japan. The tonnage of imports of sulfuric acid was 3.5% more than that of 1999, but the value of imported sulfuric acid decreased by 34%.

World Review

The global sulfur industry remained divided into two sectors—discretionary and nondiscretionary. In the discretionary sector, the mining of sulfur or pyrites is the sole objective; this voluntary production of native sulfur or pyrites is based on the orderly mining of discrete deposits, with the objective of obtaining as nearly a complete recovery of the resource as economic conditions permit. In the nondiscretionary sector, sulfur or sulfuric acid is recovered as an involuntary byproduct, the quantity of output subject to demand for the primary product irrespective of sulfur demand. Nondiscretionary sources represented nearly 87% of the sulfur in all forms produced worldwide as listed in table 12.

With the termination of Frasch production in the United States, Poland was the only country that produced more than 1 Mt of native sulfur by using either the Frasch or conventional mining methods (table 12). Small quantities of native sulfur were produced in Asia, Europe, and South America. The importance of pyrites to the world sulfur supply has significantly decreased; China was the only country in the top 15 sulfur producers whose primary sulfur source was pyrites. About 71% of all pyrites production was in this country.

Of the 25 countries listed in table 12 that produced 400,000 t or more of sulfur, 18 obtained the majority of their production as recovered elemental sulfur. These 25 countries produced 94% of the total sulfur produced worldwide. The international sulfur trade was dominated by a limited number of exporting countries, which, in descending order of importance, were Canada, Russia, Saudi Arabia, Japan, and the United Arab Emirates; these countries exported more than 1 Mt of elemental sulfur each and accounted for 64% of total sulfur trade. Major sulfur importers, in descending order, were China, Morocco, the United States, India, Tunisia, and Brazil, all with imports of more than 1 Mt.

World production of sulfur was virtually the same in 2000 as it was in 1999; consumption was believed to be slightly higher. Statistics compiled by CRU International Ltd. showed 1998 to be the seventh consecutive year in which sulfur supplies exceeded demand. Although complete data for 1999 and 2000 were not available, it could be assumed that 2000 represented the ninth consecutive year of excess sulfur supplies (Kitto, 2000).

Prices in most of the world were believed to have averaged higher throughout the year, but with a slight decrease at yearend. Production of native sulfur was 20% lower than that of 1999 as a result of termination of mining in the United States. Frasch production in Poland increased by 17%, the first increase there since 1995. Recovered sulfur production increased slightly and byproduct sulfuric acid production decreased by about 4% from those of 1999. Supply continued to exceed demand; worldwide sulfur inventories increased, much of which was stockpiled in Canada. Globally, sulfur from pyrites decreased by 13%, much of which was a result of the continued decline in China and the conversion of a pyrite-based sulfuric acid plant in Spain to a sulfur burner.

Statistics compiled by the Oil & Gas Journal showed the

Digitized by Google

United States producing 20% of the world's total refining capacity and 42% of the world's sulfur recovery capacity derived from oil refineries. The publication listed 742 oil refineries in 114 countries; only 54 of these countries were reported to have sulfur recovery capacity (Stell, 2000, p. 67-68). Although the sulfur recovery data appeared to be incomplete, analysis of the data showed that most of the countries reporting no sulfur recovery at refineries were small, with developing economies and limited refining industries. In general, as refining economies improve and the refining industries mature, additional efforts are made to improve sulfur recovery and atmospheric emissions.

Mergers of major oil producers were not limited to the United States. Following the merger in 1999 of France's Total and Belgium's Compagnie Financère Belge des Pétroles (PetroFina) to form TotalFina, the new company merged with Société Nationale Elf Aquitaine to form Total Fina Elf S.A. (TotalFinaElf). The deal formed the world's fourth largest oil company. For approval by the European Commission, TotalFina was required to divest some of its assets in France. TotalFinaElf owned 55% of France's refining capacity (Chemical Market Reporter, 2000a).

Regulations were enacted in many countries limiting the amount of sulfur allowable in fuels and the quantity of sulfur dioxide emitted into the atmosphere. Many of these regulations will result in increased sulfur recovery. Bulgaria, Canada, China, the European Union (EU), Thailand, and the United States set or proposed significant, although varied, reductions in the sulfur content of motor fuels sold in those countries. Suppliers were required to met these new standards by between 2005 and 2011. Germany, already covered under EU regulations, accelerated the timetable for new EU guidelines to be met in Germany to 2001 and was pushing for more stringent limitations in the EU's next round of rulemaking (Sulphur, 1999d). Based on Germany's urgings, European oil industry experts expected sulfur in gasoline to be reduced to 10 ppm by 2003. Germany was suggesting sulfur-free fuels throughout the European Union by 2007 (Cunningham, 2000b, p. 14). The Japanese auto industry proposed further cuts to the sulfur level of motor fuels in Japan. Allowable sulfur in gasoline was 100 ppm with reduction to 50 ppm set for 2005. The new proposal suggested limiting sulfur to 5 to 10 ppm. No timeframe for implementation was established (Sulphur, 2000k). At the 2000 European Oil Refining Conference, discussions addressed additional legislation to further limit sulfur in fuels. Legislation enacted in 1999, which would take effect in 2000, reduced the allowable sulfur in nonmotor heavy fuel oils to 1% (Cunningham, 2000b, p. 13).

European refineries faced challenges in upgrading to meet new fuel specifications. Premium prices charged for cleaner fuels were not expected to make up for the poorer yields and higher processing costs resulting from deeper desulfurization. Upgrading a typical refinery in Europe was estimated to cost more than $100 million (Packer, 2000). Total cost estimates of new European fuel specifications, including reduced sulfur content, could approach $9 billion. Increased costs would include expenditures needed for installing new facilities; modifying existing plants; increased operating expenses; new maintenance, insurance, and overhead charges; and storage fees for seasonal products (Richardson and du Preez, 2000). A European petroleum industry expert estimated that the total worldwide cost of producing low-sulfur motor fuels could approach $2.5 trillion (Sulphur, 2001).

The next targets for this type of legislation were expected to be marine bunker fuels, fuels used by ocean going vessels. The International Maritime Organization—the international governing organization for shipping—had set a 4.5% sulfur specification for these heavy fuel oils. The average sulfur content of bunker fuels was considerably less at about 3%; but even at that level, the emissions from bunker fuel were around 4 Mt/yr of sulfur in sulfur dioxide. The European Union was considering the imposition of more stringent sulfur restrictions on fuels used in ships traveling in the English Channel, the Baltic Sea, and the North Sea because shipping has become the source of an increasingly large portion of sulfur dioxide emissions in Europe. From 1990 to 2000, the shipping portion of European sulfur dioxide emissions increased from 10% to 30%. The major factor contributing to this increase was that emissions from motor vehicles had decreased. Negotiations for establishing worldwide marine fuel requirements were expected to be contentious and time-consuming. Local restrictions were likely to be imposed prior to international agreements being reached. After bunker fuels were addressed, more controversy was expected when the sulfur content of jet fuel was debated (Sulphur, 2001b). The U.S. Air Force and the U.S. Department of Energy were assessing the reduction of the sulfur content of jet fuels as a first step toward decreasing sulfur dioxide emissions from advanced propulsion systems. The research was aimed at understanding how sulfur compounds in jet fuels affect engines and emission control systems before mandating reduced sulfur levels in jet fuels (Sulphur, 2000e).

In many countries, companies were installing additional capacity for recovering sulfur and byproduct sulfuric acid, as well as producing low-sulfur fuels in advance of new government mandates and/or before legal requirements of existing laws took effect. Firms in Canada, Egypt, Germany, the Netherlands, Russia, the United Arab Emirates, the United States, and Uzbekistan were reducing sulfur dioxide emissions at their facilities. Low-sulfur fuels were offered years in advance of legal requirements in Bahrain, Kuwait, the United Kingdom, and the United States.

Not all of these developments caused significant increased production, but most created at least incremental additions to sulfur supplies. These increases in sulfur recovery, coupled with the widespread trend toward higher sulfur content in crude oils, promised continued growth in worldwide production of recovered sulfur and byproduct sulfuric acid. Only discretionary sulfur production was expected to decrease.

Australia.—Technical problems seemed to be resolved for most of Australia's nickel laterite projects using a pressure acid leach process (PAL). The PAL represented a potential demand for large quantities of sulfur to produce the sulfuric acid needed for the process. In PAL operations, nickel laterite ore slurries were leached with sulfuric acid at up to 250° C, in a titanium clad autoclave. Sulfuric acid consumption could be up to 30 t of acid per ton of metal produced—enough to justify the installation of a sulfur-burning sulfuric acid plant (Sulphur, 2000i).

QNI Pty. Ltd. and Comet Resources Ltd. planned a PAL project in Western Australia (QNI Pty. Ltd., 2000). Anaconda Nickel Ltd. was working on three PAL projects. The Murrin Murrin project achieved design capacity during the year and proceeded with its second stage of development. The company's Mount Margaret project was under development and

Digitized by Google

expected to quickly achieve design capacity taking advantage of the lessons learned at Murrin Murrin. Mount Margaret was to begin construction early in 2001, with commissioning and production beginning in 2003. A third operation, Cawse, was planned to begin in 2004 (Cunningham, 2000a).

The world's largest single-stage sulfuric acid plant provided all the acid required for stage I at Murrin Murrin. Additional acid would be required from another acid plant or byproduct acid from local sources to meet requirements for stage II. Sulfuric acid plants were planned for the other projects (Cunningham, 2000a).

Estimates placed the sulfur requirements for each planned acid plant at between 500,000 to 750,000 t/yr of sulfur. Total requirements for the Anaconda projects were expected be between 2.5 to 3 Mt/yr of elemental sulfur within 5 years. Anaconda was considering the development of a phosphate fertilizer project in the same region to make better use of the infrastructure built to support the nickel projects. The phosphate project would require an additional 400,000 to 500,000 t/yr of sulfur. Canada has provided much of the sulfur for the new Australian demand, but diversified markets were being pursued, with Middle Eastern sulfur likely offering competition for Canadian suppliers (Cunningham, 2000a).

Bahrain.—Bahrain Petroleum Co. planned to update its refinery to produce diesel fuel containing between 50 to 500 ppm sulfur. Hydrogen cracking would reduce sulfur from 7,500 ppm. Bahrain processed crude oils from its own oilfields, from off-shore operations shared with Saudi Arabia, and from Saudi Arabian crudes (Sulphur, 2001c).

Canada.—Second only to the United States in sulfur production in all forms, Canada led the world in the production of byproduct sulfur, exports of elemental sulfur, and stockpiled material. The majority of the sulfur production came from natural gas plants in Alberta where sulfur inventories reached 13.2 Mt (PentaSul North America Sulphur Review, 2001).

In addition to the large reserves of high-sulfur natural gas, Alberta has huge deposits of oil sands with estimated reserves of 300 million barrels of recoverable crude oil that also contain 4% to 5% sulfur (Stevens, 1998). As traditional petroleum production in Canada declined, oil sands were becoming a more important source of petroleum for the North American market (Cunningham, 2001) The Athabasca oil sands were a mixture of sand, water, clay, and bitumen, a naturally occurring viscous mixture of heavy hydrocarbons. Because of its complexity, bitumen was difficult or impossible to refine at most oil refineries. It was upgraded to a light-oil equivalent before further refining or was processed at facilities specifically designed for processing bitumen. Oil sands with more than 10% bitumen were considered rich; those with less than 7% bitumen were not economically attractive (Oil & Gas Journal, 1999).

Shallow deposits were amenable to strip mining, but deeper deposits required in situ technology whereby the bitumen was separated underground from the matrix that contained it with steam injection. Bitumen was separated from the oil sands matrix by mixing it with heated water. With in situ operations, steam assisted gravity drainage flushed the hydrocarbon out of the matrix, forming a pool that was pumped from the ground and transported to an upgrader via pipeline. During upgrading, the very large hydrocarbon molecules were reduced, creating molecules that are more easily processed. Furnace treatment produced petroleum coke that was used in other industries. Hydrogen addition or hydrogen conversion inserted additional hydrogen atoms into the bitumen molecules and, in the process, broke them down into smaller compounds and removed much of the sulfur. The simplified hydrocarbon, known as synthetic crude oil, was then processed at traditional refineries (Cunningham, 2001).

Three surface operations were in production or under development in Alberta and at about 75 in situ projects. Surface minable reserves were estimated to be 33 billion barrels (Gbbl) with less than 9.9 Gbbl under development. Estimates for reserves appropriate for in situ processes were 142 Gbbl. Production of sulfur from oil sands could approach 2 Mt/yr by 2015 based on projections for oil sands production. Where the sulfur was actually produced depended on the type of upgrader chosen. If a coker was installed, the sulfur could be contained in the petroleum coke product and recovered at the location where the coke was consumed. If hydrocracking was used, then the sulfur was recovered on site (Cunningham, 2001).

Syncrude Canada Ltd. began production at its Aurora Mine in August. The company's second oil sands mine, about 35 km from its existing operation near Fort McMurray, Alberta, was the first such operation to be remote from most necessary processing facilities. Syncrude used newly developed technology that allowed partial processing of the mine output before transporting bitumen froth by pipeline to the company's Mildred Lake operation for further upgrading. Syncrude used a its newly developed low energy extraction process that removed the bitumen from the sand at much lower temperatures than that required by more tradition processing techniques, cutting energy consumption by about 40% (Syncrude Canada Ltd., 2000). The company stored the sulfur recovered at the upgrading facility (Syncrude Canada Ltd., [undated], Sulphur and nitrogen removal, accessed June 27, 2001, via URL http://www.syncrude.com). Logistical problems at Fort McMurray made it difficult and costly to get the sulfur produced to market. Rail lines did not connect to the plant site, necessitating the trucking of sulfur through the town to reach the railhead (North America Sulphur Service, 2000c). Syncrude provided space for Alberta Sulphur Research Ltd. to test its underground sulfur storage method. The sulfur stocks to be tested were buried in 1999, with several years of environmental evaluation planned (Sulphur, 1999c).

Albian Sands Energy Inc., a joint venture of Shell Canada Ltd. (60%), Chevron Canada Resources Ltd. (20%), and Western Oil Sands Inc. (20%), began construction on all aspects of its Can$ 3.5 billion oil sands project in northern Alberta. The project included the Can$1.8 million Muskeg River Mine, 75 km north of Fort McMurray; the Can$1.7 million upgrade at Shell Canada's Scotford refinery near Fort Saskatchewan, Alberta; and Corridor Pipeline Ltd.'s 450-km dual pipeline system to carry diluted bitumen from the mine to Scotford and transport diluent to the mine. The pipeline project included a 43-km pipeline to carry feedstock from other operations to the upgrader and deliver upgraded material to the refinery and terminals near Edmonton, Alberta (Oil & Gas Journal, 2000d). The construction was proceeding on schedule with production expected to begin by the end of 2002 (Albian Sands Energy Inc., 2000). Albian Sands' plans included production of 500,000 t/yr of molten sulfur that would be recovered at the Scotford Refinery (North American Sulphur Service, 1999b).

Koch Industries, Inc.'s, TrueNorth Energy L.P. subsidiary expanded its Fort Hill oil sands project leases to bring the total

Digitized by Google

minable reserves at the operation to 2.4 Gbbl. TrueNorth expected to begin producing 95,000 bbl/d of bitumen by 2005. Production at the site could continue at that rate for 60 years. No upgrade was planned for the project (Sulphur, 2001f). Petro-Canada was considering the construction of a bitumen upgrade at its Edmonton, Alberta, refinery to handle production from its McKay River oil sands project near Fort McMurray. The refinery processed synthetic crude at Syncrude Canada Ltd.'s plant at Fort McMurray (Sulphur, 2000o).

Irving Oil Ltd. was spending Can$1 billion to upgrade its Saint John, New Brunswick, refinery to meet Canada's gasoline sulfur specifications that go into effect in 2005. The upgrade was to reduce sulfur dioxide emissions at the refinery and improve the reliability of environmental controls. Reductions in atmospheric sulfur dioxide emissions were self-imposed. The refinery already met New Brunswick and Canadian regulations (Goodwin, 2000).

Chile.—Corporación Nacional Del Cobre (Codelco) and Finland's Outokumpu Oyj agreed to work together to develop new flash smelting technology to modify Codelco's Chuquicamata smelter. The upgrade at the smelter would significantly decrease sulfur dioxide emissions (Outokumpu Oyj, 2000). Outokumpu also was considering the construction of a copper smelter in Mejillones. Upon completion sometime after 2003, the smelter would have the capacity to produce 350,000 t/yr of copper and 1 Mt/yr of sulfuric acid (Sulphur, 2000c).

Noranda Inc. of Canada was expanding its Altonorte smelter to increase copper production by about 80%. Sulfuric acid production capacity, however, will nearly triple to 700,000 t/yr. The upgrade would make Altonorte more cost competitive and enable the company to capture 90% of the sulfur dioxide released by the smelter. The complete modernization project was expected to be completed in 2003 (Sulphur, 2000n).

China.—One of the few countries whose primary domestic source of sulfur was pyrites, China was working to convert much of its sulfuric acid capacity from pyrites burning to elemental sulfur. Some new elemental sulfur-based acid plants were built, but much of the conversion was through adapting existing pyrites operations to use solid sulfur. The conversions were driven by economic and environmental reasons (Fertilizer Markets, 1999). Environmental awareness was a relatively recent concern in official Government considerations. Pyrite-based sulfuric acid plants in China emitted sulfur dioxide and other pollutants to the atmosphere, discharged pollutants to rivers and contaminated groundwater, and presented solid waste disposal problems. A properly operated sulfur-burner has very limited atmospheric emissions, no water discharge, and no solid waste issues (Sears, 2000).

The Chinese pyrite industry faced additional setbacks when Nanjing Chemical Industry Group, a leading producer of sulfuric acid, announced plans to switch to elemental sulfur burning. The reconstructed plant was to use sulfur recovered from Chinese oil refineries (Sulphur, 2001i). The China Sulphuric Acid Industry Association forecast sulfuric acid production to grow to 28 Mt in 2005 from 23 Mt in 2000, representing an increased sulfur demand of about 1.7 Mt (Sears, 2000).

The Chinese petroleum industry was working to modernize its facilities to reduce sulfur emissions as it increased imports of sour crudes from the Middle East (Sulphur, 2001i). Chinese imports of crude oil have been sweet crudes because of the country's inadequate sulfur recovery capabilities. Work was progressing to improve sulfur recovery units at several refineries. Additional improvements at smelters were expected to increase availability of byproduct acid (Sears, 2000)

Chinese crude petroleum was relatively sweet with little sulfur recovered at refineries. In fact, only 1 of China's 95 refineries had any sulfur recovery capacity, amounting to just more than 100,000 t/yr. Restructuring of the refining industry included plans for large-scale increases in sulfur recovery capacity. Joint ventures with major oil producers willing to make investments in the Chinese industry were a large part of the strategy for reducing imports of oil products and improving the refining technology (Cunningham, 1999a).

Germany.—As one of the largest sulfur producing countries in Europe, discrepancies existed between official Government production statistics and other sources reporting German production. Other sources showed German production significantly higher than Government sources, with nearly 1 Mt more production of sulfur in all forms than official data. Most German sulfur was sold in European Union markets. Although official U.S. Census Bureau statistics suppressed data regarding United States imports from Germany, the United States was believed to have received sulfur shipments from Germany (Fertilizer Focus, 2001).

Norddeutsche Affinerie AG completed the expansion of its Hamburg copper smelter in November. The upgrade raised the sulfuric acid capacity of the smelter to 1.3 Mt. Production was targeted toward the northwestern European markets (Fertilizer Week, 2000). Norddeutsche Affinerie was considering a further 50% expansion of its copper and sulfuric acid capacity. The expansion would bring the company's total sulfuric acid capacity to nearly 2 Mt/yr. A location for the new operation was not identified (Sulphur, 2001h).

Iran.—Major oil companies were showing increased interest in exploration in Iran. A refinery with sulfur recovery capacity was completed in Iran's Hormuzgan Province. A new gas processing plant to process natural gas from the South Pars gasfield was under construction. The sulfur recovery at the gas plant was expected to be 400 t/d. Eight phases of development were planned for the South Pars field. When development was complete, sulfur output from the field could reach 500,000 t/yr (Cunningham, 2000d) Sulfur producers in Iran were installing forming capacity to improve their competitiveness with other major sulfur exporters (Sulphur, 2000f).

Iraq.—Questions remain about Frasch and other sulfur production in Iraq. Before Iraq invaded Kuwait precipitating Operation Desert Shield in 1990 and Operation Desert Storm (the gulf war) in 1991, Frasch production at the Mishraq Mine was around 1 Mt/yr, with plans to expand capacity to 2 Mt/yr. Some recovered sulfur was also produced in Iraq. Since that time, with the imposition of economic sanctions by the United Nations (UN) and very limited public information of any kind coming from Iraq, little was known of sulfur production in that country. Mishraq was not believed to be damaged during the war and could be operating at or near capacity, although that scenario is doubtful. The most likely situation was that Mishraq produced consistently since 1990 but at a greatly reduced rate. Recovered sulfur production probably continued. With little outlet for any products as a result of the sanctions, significant stocks of sulfur were believed to have accumulated at Mishraq since the imposition of sanctions. Sulfur also was produced at two sour gas processing plants at Kirkuk and Beiji (Fertilizer

Digitized by Google

Markets, 2000b).

Iraq reached an agreement with Jordan to supply all of Jordan's sulfur requirements starting in late 2000 and through 2001. UN sanctions against Iraq ban most trade with Iraq since Iraq invaded Kuwait in 1990. Jordan invoked an article of the UN charter that allows a UN member state not to implement a sanction if it is against that country's domestic interests. The price of the Iraqi sulfur, probably from the Mishraq Frasch Mine, was estimated to be nearly one-third less than similar material from elsewhere in the Middle East (Sulphur, 2000g). Jordan received 150,000 t of sulfur from Iraq in 2000 with up to 1 Mt expected in 2001 (Fertilizer Markets, 2000b).

Kazakhstan.—The Tengiz oilfield with associated gas on the northeast shore of the Caspian Sea in western Kazakhstan has been operated by Tengizchevroil (TCO) since 1993. In 2000, Chevron Corp. raised its stake in TCO to 50%. Other owners in TCO were Kazakhoil (the Republic of Kazakhstan's national oil and gas company with 20%), ExxonMobil (25%), and LUKARCO (a joint venture between BP and Russian oil company LUKoil with 5%) (Chevron Corp., 2000a). One of the world's largest oilfields, Tengiz contains high-quality oil with 0.49% sulfur and associated natural gas that contains 12.5% hydrogen sulfide (Connell and others, 2000).

In 2000, TCO completed an oil and gas expansion project that included additional sulfur production capacity and further expansions were planned (Chevron Corp., 2000a). TCO was studying the feasibility of reinjecting sour gas into the Tengiz reservoir and reducing the quantity of sulfur recovered at the site (Chevron, 2000b, p. 23). Sulfur production at Tengiz was around 1.3 Mt in 2000 with likely expansion to 2 Mt by 2005 and the potential to reach 3.8 Mt by 2010 (Cunningham, 2000e).

Mexico.—A former Frasch producer from 1954 when mining began at San Cristobal (Larson and Marks, 1955, p. 1136-1137) until 1993 when the Texistepec Mine closed (Ober, 1994, p. 1172), Mexico was the second largest supplier of imported recovered sulfur to the United States. Mexico recovered most of its sulfur from its petroleum refineries and recovered byproduct sulfuric acid at its smelters.

Mexican crude oil was classified in four specific types. With production of 1.5 million barrels per day, maya crude was the type with highest production and lowest quality. Maya crude was heavy, making it difficult to refine at conventional refineries, and had an average sulfur content of 3.4%. Second in production at 950,000 bbl/d, isthmus crude had medium weight and sulfur content of about 1.4%. Marine light contained 1.23% sulfur and production was 721,000 bbl/d. Olmeca, the highest quality Mexican crude with 0.93% sulfur, had the lowest production at 455,000 bbl/d. Pemex refineries processed about 45% of domestically produced crude oil. The remainder was exported; primary customers, in descending order, were the United States, Spain, the Netherlands Antilles, and Japan (Manriquez and others, 2000).

Although Mexico produced about 5% of global crude oil, it did not have the refinery capacity to meet domestic demand for gasoline. The completion of the refinery upgrade at Pemex's Cadereyta refinery brought capacity close to demand. Five additional upgrade projects were planned to transform the country's trade balance for gasoline. Mexican refineries were unable to process heavy maya crude into sufficient quantities of motor fuels. Pemex invested in U.S. refineries in Texas to ensure steady markets for their crude oil but had been unable to find the capital to modernize its own refineries. Revamping at Cadereyta expanded capacity for diesel, jet fuel, and gasoline. Sulfur production was expected to be about 480 t/d with further expansion of 80 t/d, eventually reaching about 450,000 t/yr. Sulfur production was expected to be similar when the Madero upgrade was completed. Other planned modernization projects include those of Minatitlan, Salamanca, Tula, and Salina Cruz. No details on progress or expected sulfur recovery capacities were available. Additional sulfur supplies were expected from new natural gas processing operations, perhaps more than 500,000 t/yr from a single project (Cunningham, 2000c).

Pemex had long-term supply contracts with U.S. refiners Premcor Inc., ExxonMobil, and Marathon Ashland Petroleum LLC (Cunningham, 1999b). Pemex was involved in a joint venture with Shell at Deer Park, TX (North America Sulphur Service, 1999a).

Netherlands Antilles.—PdVSA's Netherlands Antilles affiliate, Refinería Isla, was upgrading its refinery in Curaçao, including its sulfur recovery unit. Completion was expected in 2002 (Sulphur, 2000v).

Philippines.—Crew Development Corp. of Canada was planning a nickel pressure acid leach project on Mindoro Island in the Philippines. In order to mitigate the costs of sulfur, a high-cost factor in development of the nickel operation, Crew investigated the possibility of mining sulfur from the Pamplona sulfur deposit on Negros Island, also in the Philippines. Reserves at Pamplona were set at 60 Mt with 30.8% sulfur, 13.8% of which was elemental sulfur and 17% was in sulfides (Industrial Minerals, 2000). With sulfur prices at low levels worldwide and no change expected, it seemed unlikely that the Philippine sulfur deposit would be developed. The cost of development and production would need to be very low to allow profitable processing.

Poland.—As in many countries with improving economies, oil refineries in Poland were upgrading their sulfur recovery units to meet air quality regulations forbidding the release of sulfur dioxide into the atmosphere (Sulphur, 1999b). Recovered sulfur, however, remains a secondary source of sulfur in Poland.

Rich sulfur deposits were discovered in Poland in 1954, and production began at the first surface mine late in that decade. Since that time, five native sulfur mines have been developed in Poland. The first two, Piaseczno and Machów, were surface mines that utilized conventional mining methods. The other three mines, Grzybów, Jeziórko, and Osiek, used the Frasch method with modifications to work with the geologic conditions in Poland. At the peak of Polish sulfur production in 1980, more than 5 Mt of sulfur could be produced from three mines, Grzybów, Jeziórko, and Machów. Three of the mines closed and were being recultivated as lakes and other recreation areas, leaving Jeziórko and Osiek operating in 1999 (Karolak, 1997).

Polish sulfur entered the global market in 1961, when the sulfur shipping facilities in Gdańsk were completed. In 1980, about 3.8 Mt (nearly 75%) of Polish production was exported, mostly to other European countries. Since the early 1990s, low global prices have made it extremely difficult for the discretionary sulfur producers to compete in the global market, and those markets have dwindled for the Polish industry (Karolak, 1997). Polish Frasch production increased by 17% in 2000, the first increase since 1995. Domestic consumption and exports were higher than the previous year. Poland's largest sulfur customer was Morocco; Poland had a sulfur-phosphate rock swap agreement with a Moroccan phosphate producer

Digitized by Google

(Fertilizer Focus, 2001).

Qatar.—Qatar Liquified Gas Co. was revamping and expanding two sulfur recovery units at Ras Laffan, with completion expected in 2002 (Sulphur, 2000y).

Russia.—The Astrakhan Gas Processing Plant (AGP) was the largest single source of recovered sulfur in the world. During 2000, the operation was producing 3.6 Mt/yr and expansion projects nearing completion promised to bring the total to 4.2 Mt/yr by 2002. Final expansions were expected to be completed in 2003, bringing sulfur production to 4.5 Mt/yr. Formed sulfur from this site was exported through the port of Novorossiysk, at which a liquid sulfur terminal was under consideration. Exports of AGP products from this port were limited to about 1 Mt/yr because the rail line from the plant to the port was unable to handle more than that (Sulphur, 2000m).

Russia's largest natural gas producer, Gazprom, approved a study on the feasibility of building a liquid sulfur terminal at the Black Sea port of Novorossiysk to handle 1 Mt/yr of molten sulfur from Gazprom's Astrakhan natural gas field. North Africa and other locations in the Mediterranean would be logical markets for the material. In 2000, Astrakhangazprom produced about 3.6 Mt with sales of 3.9 Mt of solid sulfur, including sales from stocks (Sulphur, 2000d).

Russian exports were more than 3 Mt in 2000. The 25% increase from the previous year was a result of increased production from Astrakhan and an effort to reduce stocks. Israel was Russia's largest customer. Russian sulfur has displaced material from Canada and the Middle East in important markets in north Africa, southern Europe, and the Mediterranean area (Fertilizer Week, 2001).

Russian industry was beginning to deal with pollution issues, sometimes with foreign assistance. Perneftegas, a major Russian natural gas and oil producer, revamped one of its units to reduce sulfur dioxide emissions (Sulphur, 2000m). The copper smelter at Karabash, one of Russia's five most polluted cities, was renovating the gas cleaning systems to recover sulfuric acid. The Government of Norway was paying for environmental improvements at the Pechanganickel operation owned by Norilsk Nickel Corp. on the Kola Peninsula. Sulfuric acid recovery was to be expanded to reduce the amount of sulfur dioxide released in Russia that contaminates other countries that border Russia (Sulphur, 2001g).

Saudi Arabia.—The Hawiyah gas plant in Saudi Arabia was 4 months ahead of schedule and was expected to begin production in December 2001. Ramp-up was expected to begin in June. This was the first supply plant of Saudi Arabia's master gas system to process gas not associated with crude oil production (Sulphur, 2000u).

Spain.—A new 900,000 t/yr sulfuric acid plant was commissioned by Fertiberia S.A. at Huelva in southern Spain. The new sulfuric acid plant was expected to use about 200,000 t/yr of elemental sulfur from Spanish suppliers and imported sulfur from Canada, France, and Russia (Fertilizer Markets, 2000a). The new sulfuric acid plant replaced three pyrite-based acid plants (Fertilizer Focus, 2001)

Spain's Asturiana de Zinc, S.A., was building a new zinc processing plant in San Juan de Nieva. Included in the project was a sulfuric acid plant (Sulphur, 2000j).

Ukraine.—Ukraine, once a major producer of native sulfur using Frasch and conventional mining methods, has not mined any sulfur for several years. The country planned to flood one of its idle surface mines to be used as a reservoir (Sulphur, 2000m).

Venezuela.—Venezuela's Orinoco Basin was one of the world's largest resources of crude oil. If recent developments in refining technology had not provided the means for upgrading the crude, it could not have been developed (Sulphur, 2000s). Upgraded crude production from the Orinoco Basin could result eventually in the production of 8 Mt/yr of sulfur, with about 5 Mt/yr of that being produced in Venezuela, and the rest, at refineries in other countries, very possibly in the United States (Cunningham, 2000e).

Heavy oil upgrading facilities at the port of Jose progressed. The first of the projects to upgrade high-sulfur Orinico crude oil was expected to be completed early in 2001. Petrozuata, a joint venture between Conoco Inc. and PdVSA that was designed to produce synthetic crude oil for domestic refining and export, would also produce byproduct petroleum coke and elemental sulfur. The Cerro Negro project, owned by ExxonMobil, PdVSA, and Germany's Veba Oel AG, will produce synthetic crude oil for refining at ExxonMobil's and PdVSA's refinery in Chalmette, LA, and in Germany. Production was expected to begin in 2001. The largest upgrader project at Jose is scheduled for completion in 2002. That operation is owned 47% by TotalFinaElf, 38% by PdVSA, and 15% by Statoil ASA of Norway (Sulphur, 2001e).

Sulfur production from the first heavy oil upgrader project at the Jose complex will undergo a forming process before being shipped overseas. Once the heavy oil upgrading projects are completed at Jose, the terminal will provide an additional 400,000 t/yr of sulfur to the world market (Sulphur, 2000h).

PdVSA also is involved in a joint venture for processing Venezuelan crude at the Phillips refinery in Sweeny, TX. PdVSA and Phillips spent $540 million to build a coker and a vacuum distillation unit to be operated by Merey Sweeny Limited Partnership (Sulphur, 2001e).

In addition to upgrader projects that will add sulfur recovery capacity in Venezuela, PdVSA was updating existing petroleum crackers to meet new standards for reducing sulfur emissions. The upgrade was designed to raise the recovery at two refineries to 99.2% from a maximum of 94%. Venezuela established new standards of 98.9% recovery (Chemical Market Reporter, 2000b).

Zambia.—Roan Antelope Mining Corp. of Zambia planned to develop of a new SX-EW project at its Muliashi North Mine. The project required construction of an elemental-sulfur-based sulfuric acid plant (Sulphur, 2000t).

Current Research and Technology

Biodesulfurization.—Enchira Biotechnology Corp. received $900,000 from the U.S. Department of Energy for research to develop a bacterial process for removing sulfur from gasoline. Enchira, formerly Energy Biosystems Corp., was operating a pilot plant in Alaska to remove sulfur from diesel using a similar process. Thus far, the diesel process had struggled to meet cost targets and did not remove sulfur as thoroughly as projected. Enchira has stated that because gasoline is a more powerful solvent than diesel, it may be difficult to adapt the process to gasoline. Genetic modifications to the bacteria enabled faster adaptation to differing environments (Sulphur, 2000b).

Development of a biological process that worked quickly enough to use in an industrial facility had been the major hurdle

Digitized by Google

to implementation. Biocatalytic desulfurization, when fully developed, was expected to be significantly less costly than more common technology and was identified as a possible way for small refiners to meet more stringent sulfur requirements (U.S. Department of Energy, 2000).

Injection of Sulfur Dioxide.—Alberta Sulphur Research Ltd. was looking into the possibility of developing a process for injecting sulfur dioxide into a sour gas reservoir. The sulfur dioxide would react with the hydrogen sulfide in the deposit to form elemental sulfur and water, the same reaction used in sulfur recovery units. Not only would the process eliminate a sulfur disposal problem for the operation, but it also would produce high quality steam that could be used elsewhere in the operation. This process also could help to eliminate excess stocks of sulfur and at the same time produce electricity for sale to the power grid. Investigation of this new idea for sulfur disposal has just begun; but if it is successfully developed, it could relieve the worldwide oversupply situation (Connock, 2001).

New Processes for Removing Sulfur from Fuels.—BP developed a gasoline desulfurization process called olefinic alkylation of thiophenic sulphur (OATS). OATS was capable of removing 99.5% of the sulfur compounds in a major gasoline blending component, naptha produced at fluid catalytic cracking units, without significantly reducing the quality of the fuel or reducing the quantity of fuel produced. The OATS process was simple and easily retrofitted to an existing operation. The process involved pretreatment of the feed by washing with acid, neutralization of the spent liquor, the OATS reaction section, the production fractionation section, and a naptha hydrotreater. Two small demonstration units began operation at BP's Texas City, TX, refinery, and a larger scale trial was completed at the company's joint-venture refinery in Bayern, Germany (Sulphur, 2001d). ExxonMobil has developed a new catalyst for conventional hydrotreating processes, but it minimizes quality degradation of the product (Exxon Mobil Corp., 2000).

Phillips Petroleum developed a process that stripped sulfur from gasoline blending stocks by using a regenerative adsorbent. The benefits of this process as compared with some desulfurizing processes were that the reduction in octane level was limited, the volume loss was low, and the vapor pressure was maintained. The process's first commercial application at Phillips Petroleum's Borger, TX, facility was set to go onstream in early 2001. Phillips Petroleum licensed the technology to Marathon Ashland Petroleum for use at all of its seven refineries (Sulphur, 2000q).

Phillips Petroleum adapted its S Zorb technology to handle diesel fuels. Pilot plant testing of the processes was ongoing at the company's research and development center. The S Zorb technology did not consume significant quantities of hydrogen, a high-cost component of many desulfurization processes (Sulphur, 2000p).

Reinjection of Hydrogen Sulfide.—Reinjection of the sulfur as hydrogen sulfide into an appropriate underground reservoir was an attractive alternative in some instances at some natural gas operations but was seldom feasible at oil refineries. In acid gas reinjection from sour gas processing, the hydrogen sulfide and carbon dioxide were separated from the gas using standard separation techniques and recompressed into a suitable injection zone. The suitability of the injection zone was influenced by its distance from the processing facility and could be a large aquifer, a depleted reservoir, or a zone producing sour fluids. A depleted reservoir was especially attractive because its size and original pressure were already known, making the determination of its holding capacity easier to determine. The sour gases also could be reinjected into a producing deposit.

Reinjection was being used at many small-scale operations, especially in Canada, but it had not been demonstrated that reinjection would work on a large scale. It was essential that the reinjected gases not escape from the reservoir by migration into adjacent reservoirs or aquifers or into the atmosphere by migration through an outcrop.

With large-scale reinjection schemes, the energy balance would be a large factor in determining its feasibility. Without the sulfur recovery plant that produces energy that can be used elsewhere in the operation, steam production using an external energy source, such as natural gas or electricity, was required. Using natural gas presented the situation of producing carbon dioxide emissions in order to reinject carbon dioxide. A determination on whether the environmental benefit of reinjecting carbon dioxide was canceled out by the carbon dioxide emissions produced for that reinjection was needed.

A feasibility study conducted by Abu Dhabi National Oil Co. showed that a large scale reinjection project should have favorable energy balance greenhouse gas considerations. The technical and operating challenges were yet to be resolved (Connock, 2001).

Sulfuric Acid from Powerplants.—Powerspan Corp. developed a process for converting sulfur dioxide emissions from coal-fired power generation to commercial grade sulfuric acid. A full-scale demonstration project was being installed at FirstEnergy Corp.'s Eastlake, OH, generating plant. The electrocatalytic oxidation process (ECO) was designed to cut nitrogen oxide and sulfur dioxide emissions simultaneously at lower installation and operation costs than similar emission reduction processes. The Eastlake project was expected to cut nitrogen oxide, sulfur dioxide, mercury, and fine particulate matter emissions by more than 70%, 50%, 70%, and 90%, respectively, beginning early in 2001 (Sulphur, 2000r).

Sulfur Paving Materials.—Liquified Gas, a subsidiary of Astrakhangazprom, built a pilot plant to produce materials for trials of sulfur-extended construction materials. The plant will have the capacity to produce 50,000 t/yr of sulfur polymer cement and 32,000 t/yr of sulfur-extended asphalt cement. Other countries of the former Soviet Union that announced plans to pursue the use of sulfur in paving are Turkmenistan and Kazakhstan (Sulphur, 2001a).

Outlook

The sulfur industry continued on its path of increased production, slower growth in consumption, higher stocks, and expanded world trade. U.S. production from petroleum refineries is expected to increase substantially in the next few years as expansions, upgrades, and new facilities at existing refineries are completed, enabling refiners to increase thoughput of crude oil and to process higher sulfur crudes. Production from natural gas operations varies but is usually between 2.0 and 2.2 Mt/yr. Output is expected to remain at about that level. Worldwide recovered sulfur should continue to increase. Refineries in developing countries should begin to improve environmental protection measures and eventually approach the environmental standards of plants in Japan, North America, and Western Europe.

Digitized by Google

Experts from the natural gas industry estimate that the world demand for natural gas will grow by 2.5% per year during the next 20 years, a total 50% increase in demand. Producing 50% more gas means recovering at least an additional 50% in sulfur from that source. Future gas production, however, is likely to come from deeper, hotter, and sourer deposits that will result in even more excess sulfur production unless more efforts are made to develop new, large-scale uses for sulfur. Other alternative technologies for reinjection and long-term storage to eliminate some of the excess sulfur supply will require further investigation in order to handle the quantity of surplus material anticipated (Hyne, 2000).

Byproduct sulfuric acid production will remain depressed in the United States as long as the copper smelters remain idle. With the copper industry's switch to lower cost production processes and producing regions, it could be many years before U.S. byproduct acid production again approaches the level it reached in 1998. Worldwide, the outlook is different. Copper production costs in many countries are lower than in the United States, so that acid production from those countries has not decreased as drastically, and increased production is more likely. Environmental controls have been less of a concern in developing countries in the past. Many copper producers, however, in these and even in developed countries are installing more efficient sulfuric acid plants to limit sulfur dioxide emissions at new and existing smelters. Planned and in-progress improvement projects could increase byproduct acid production to 52 Mt by 2010 or the equivalent of about 17 Mt of sulfur from 10 Mt (3.3 Mt of sulfur) in 1999 (Sulphur, 1999a).

Frasch and pyrites production, however, have little chance of significant long-term increases. Because of the continued growth of elemental sulfur recovery for environmental reasons rather than demand, discretionary sulfur has become increasingly less important. Frasch sulfur has become the high-cost process for sulfur production. Pyrites, with significant direct production costs, are an even higher-cost raw material for sulfuric acid production when the environmental aspects are considered. Discretionary sulfur output should show a steady decline. The decreases will be pronounced when large operations are closed outright for economic reasons such as was the case in 2000.

Sulfur and sulfuric acid will continue to be important in agricultural and industrial applications, although consumption will not equal production. World sulfur demand for fertilizer is forecast to increase at about 2.7% per year for the next 10 years; industrial demand is predicted to grow at 2.3% per year.

The most important changes in sulfur consumption will be in location. Phosphate fertilizer production, where most sulfur is consumed, is projected to increase by about 2.3% per year through 2010. With new and expanding phosphate fertilizer capacity in Australia, China, and India, sulfur demand will grow in these areas at the expense of some phosphate operations elsewhere, thus transferring sulfur demand rather than creating new. The effects were already being felt by the U.S. phosphate industry, reflected in the permanent closure of some facilities and reduced production at others. U.S. phosphate products supply domestic requirements, but a large portion of U.S. production is exported. China and India are primary markets for United States fertilizers. As the phosphate fertilizer industries develop in these countries, some of the markets for U.S. material could be lost. Sulfur will be required for phosphate production at new operations, and more producers will be competing for those markets.

Use of sulfur directly or in compounds as fertilizer should increase, but this use will be dependent on agricultural economies and increased acceptance of the need for sulfur in plant nutrition. If widespread use of plant nutrient sulfur is adopted, sulfur consumption in that application could be significant; thus far, growth has been slow.

Industrial sulfur consumption has more prospects for growth than in recent years but still less than agriculture and not enough to consume any surplus production. Conversion to or increases in copper leaching by producers, who require significantly more sulfuric acid for the leaching operations than was used in 2000, bode well for the sulfur industry. Nickel PAL operations were demanding increased quantities of sulfur. Changes in the preferred methods for producing oxygenated gasoline, especially in Canada and the United States, might result in additional alkylation capacity that would require additional sulfuric acid. Other industrial uses show less potential for expansion. Estimates show sulfur production exceeding consumption by 3 Mt/yr for the next 20 years, and worldwide inventories reaching 80 Mt by 2020 (Hyne, 1999). The potential exists for involuntary sulfur production of 80 to 100 Mt/yr by 2050, representing a 120% increase in the time period that could be required to develop viable energy alternatives to fossil fuels (Cunningham, 2000e)

Unless significant new uses for elemental sulfur are implemented, the oversupply situation will result in tremendous stockpiles accumulating around the world. In the 1970s and 1980s, research was conducted that showed the effectiveness of sulfur in several construction uses that held the promise of consuming huge quantities of sulfur in sulfur-extended asphalt and sulfur concretes. In many instances, these materials were found to be superior to the more traditional products, but their use has been very limited. Interest in these materials seemed to be increasing but only in additional research. No large-scale projects were announced that would require sizable quantities of sulfur. It may be necessary to revisit these proposals to avoid building mountains of sulfur in the not-too-distant future.

e/ Estimated. p/ Preliminary. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through July 20, 2001.

3/ The term "Source" reflects the means of collecting sulfur and the type of raw material. Sources listed include the following: (1) Frasch recovery, (2) native, comprising all production of elemental sulfur by traditional mining methods (thereby excluding Frasch), (3) pyrites (whether or not the sulfur is recovered in the elemental form or as acid), (4) byproduct recovery, either as elemental sulfur or as sulfur compounds from coal gasification, metallurgical operations including associated coal processing, crude oil and natural gas extraction, petroleum refining, tar sand cleaning, and processing of spent oxide from stack-gas scrubbers, and (5) recovery from the processing mined gypsum. Recovery of sulfur in the form of sulfuric acid from artificial gypsum produced as a byproduct of phosphatic fertilizer production is excluded, because to include it would result in double counting. It should be noted that production of Frasch sulfur, other native sulfur, pyrites-derived sulfur, mined gypsum-derived sulfur, byproduct sulfur from extraction of crude oil and natural gas, and recovery from tar sands are all credited to the country of origin of the extracted raw materials. In contrast, byproduct recovery from metallurgical operations, petroleum refineries, and spent oxides are credited to the nation, where the recovery takes place, which is not the original source country of the crude product from which the sulfur is extracted.

4/ Reported figure.

5/ Official Polish sources report total Frasch and native mined elemental sulfur output annually, undifferentiated; this figure has been divided between Frasch and other native sulfur on the basis of information obtained from supplementary sources.

6/ Sulfur is believed to be produced from Frasch and as a petroleum byproduct; however, information is inadequate to formulate estimates.

7/ Includes byproduct production from synthetic fuels.

8/ "Other" includes all countries, except the above mentioned: Australia, Belgium, Canada, Chile, China, Finland, France, Germany, Iran, Italy, Japan, Kazakhstan Republic of Korea, Kuwait, Mexico, Netherlands, Poland, Russia, Saudi Arabia, South Africa, Spain, United Arab Emirates, United States, Uzbekistan, and Venezuela.

9/ Includes "China, elemental" and "Iraq, elemental, all sources."

TALC AND PYROPHYLLITE

By Robert L. Virta

Domestic survey data and tables were prepared by Raymond I. Eldridge III, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

The mineral talc is a hydrous magnesium silicate. A massive talcose rock is called steatite, and an impure massive variety is known as soapstone. Talc is used commercially because of its fragrance retention, luster, purity, softness, and whiteness. Other commercially important properties of talc are its chemical inertness, high dielectric strength, high thermal conductivity, low electrical conductivity, and oil and grease adsorption. Major markets for talc are ceramics, paint, paper, and plastics.

Pyrophyllite is a hydrous aluminum silicate with a structure similar to talc. Such properties as chemical inertness, high dielectric strength, high melting point, and low electrical conductivity make it useful for ceramic and refractory applications.

Legislation and Government Programs

The National Toxicology Program (NTP) of the U.S. Department of Health and Human Services investigated the possible inclusion of "talc, asbestiform" (talc containing asbestiform fibers) and "talc, nonasbestiform" (talc not containing asbestiform fibers) in the 10th report on carcinogens for Congress. Following its review of the health and mineralogical literature, the NTP subcommittee voted five for and five against listing asbestiform talc as reasonably anticipated to be a human carcinogen in its annual report on carcinogens. Several members of the panel did not feel that human and animal data were sufficient to warrant listing in the report. The vote not to list nonasbestiform talc was seven for and three against. In this case, questions arose about possible asbestos contamination of the talc mentioned in several of the health studies cited. As a result of these votes, the panel recommended against listing asbestiform talc and nonasbestiform talc in its 10th report on carcinogens (U.S. Department of Health and Human Services, Public Health Service, 2001; National Paint and Coatings Association, January 2001, NTP skips over talc, accessed January 8, 2001, at URL http://www.paint.org/ind_issue/current/jan/issue05.htm).

In 2000, the U.S. Department of Defense authorized the disposal of 907 metric tons (t) of block and lump talc, which is the entire uncommitted inventory in that category, from the National Defense Stockpile.

Production

Talc.—In 2000, seven companies operating nine mines in five States produced soapstone, steatite, and talc. All were open pit mines. The producers were, in decreasing order of production, Luzenac America Inc., Wold Minerals Corp. (previously owned by Dal Minerals Co.), Barrett's Minerals Inc., Gouverneur Talc Co., Milwhite Inc., Suzorite Mineral Products Inc. (Zemex Corp.), and Steatite of Southern Oregon. Three other companies, CalTalc Co. in California, Unimin Texas Co. L.P. in Texas, and New World Stone Co. in Virginia worked from stocks. Barrett's Minerals, Gouverneur Talc, Luzenac America, and Wold Minerals were the largest domestic producers, accounting for more than 80% of the tonnage.

In 2000, U.S. mine production was 851,000 t valued at $22.1 million, compared with 925,000 t valued at $26.1 million in 1999 (tables 1 and 2). Production decreased in all States except Texas. Montana led all States in the tonnage and value of talc produced, followed by Texas, Vermont, New York, and Oregon. Mines operating in Montana, New York, Texas, and

Talc and Pyrophyllite in the 20th Century

In 1900, domestic production of talc was about 80,000 metric tons and pyrophyllite production was less than 5,000 tons. Prior to 1900, annual production of talc and pyrophyllite were about 50,000 tons and a few hundred tons, respectively. Talc and pyrophyllite were used interchangeably in the early part of the century. Major markets for milled talc and pyrophyllite were paper and talcum powder. Cut and shaped talc (soapstone) was used for gas tips (nozzles), laboratory benches, laundry tubs, metal worker's talc crayons, sinks, tailor's chalk, tiles, and thermal insulation panels. By the late 1920s, however, many new markets emerged, including ceramics, foundry components, lubricants, paints, roofing, rubber, textiles, and wall plaster. Ceramics, which comprised 1% of talc markets in 1931, accounted for 29% of the market by 1973. During the same time period, sales for paint applications decreased from 48% to 15%, sales for paper decreased from 16% to 7%, sales for refractories increased from 1% to 5%, sales for roofing decreased from 11% to 3%, and sales for rubber decreased from 11% to 3%. Exports accounted for less than 1% of talc sales in 1931 and 15% of sales in 1973. By the 1950s, pyrophyllite had separated itself from talc as a commodity, and its major end-use markets were insecticides (29%), rubber (24%), ceramics (21%), and refractories (13%).

In 2000, domestic production of talc was 851,000 tons, the lowest since 1974. In the past 30 years, talc sales fluctuated between 792,000 tons in 1972 to record high sales of 1.19 million metric tons in 1990. The variations in sales were generally in line with the ups and downs of the U.S. economy. Pyrophyllite production peaked in the early 1960s and then declined through the mid-1980s. Production and sales have been fairly level from the 1980s to the present. In 2000, major domestic talc markets were ceramics (28%), paint (21%), paper (20%), and roofing (8%). Major markets for pyrophyllite were, in decreasing order of consumption, ceramics, refractories, and paint.

Digitized by Google

Vermont accounted for nearly all the domestic talc production.

Domestic production data were obtained through a voluntary survey of U.S. mining companies conducted by the U.S. Geological Survey (USGS). Survey forms were sent to 12 companies. Responses accounting for approximately 79% of the data are presented in table 1; the remaining data were estimated from reported prior-year data adjusted according to industry trends.

Pyrophyllite.—Piedmont Minerals Co. Inc. and Standard Mineral Co. Inc. operated three mines in North Carolina and Standard Industrial Minerals Inc. operated one mine in California. Production of pyrophyllite decreased slightly from that of 1999.

Domestic production data were acquired through a voluntary USGS survey of the three U.S. companies that mine pyrophyllite. All responded to the survey.

Consumption

Domestic consumption data for talc and pyrophyllite were developed by the USGS from a voluntary survey of U.S. mills. Survey forms were sent to 13 companies operating 17 mills in 9 States for talc and 3 companies operating 3 mills in 2 States for pyrophyllite. Approximately 81% of the talc data presented in table 3 was reported by the companies; the remaining data were estimated from reported prior-year data adjusted according to industry trends. All the pyrophyllite producers responded to the consumption survey.

Talc.—Approximately 831,000 t of talc valued at $96.1 million was sold or used in 2000, a decrease from 881,000 t valued at $102 million in 1999. Of the 831,000 t of talc sold or used, producers reported that 732,000 t was sold for domestic use and approximately 99,000 t was exported.

Domestic markets included, in decreasing order of consumption, ceramics (sanitaryware, tiles, etc.), paint, paper, roofing, plastics, rubber, cosmetics, and refractories (table 3). Domestic sales of talc declined by 5% in 2000 compared with that of 1999. The slowdown of growth of the domestic economy had an impact on sales in the last half of 2000. Sales of talc to manufacturers of paint, sanitaryware, roofing, and tile are strongly tied to the housing industry. Initiation of new privately owned housing units declined to 1.59 million in 2000 from 1.67 million in 1999. Shipments of architectural paint, the major paint market for talc, declined to 2.52 million liters in 2000 from 2.56 million liters in 1999. Data on sales of vitreous china plumbing fixtures (commodes, sinks, urinals, water tanks, etc.) are not available for 2000, but shipments of fixtures in 1999 were less than those of 1998. Additionally, the difference between production and shipments of vitreous china plumbing fixtures was greater in 1999 than in 1998, suggesting that production in 2000 could be lower than in 1999 to avoid inventory buildup. Despite lower sales of domestically produced talc to manufacturers of plastic products, shipments of plastics have continued to increase. Shipments in 1999 were slightly more than $300 billion compared with $250 billion in 1996. Imports of talc are thought to fill much of the expanding plastics market demand for talc fillers and extenders.

About 75,400 t of talc was reported under the "Other" category by respondents in 2000. Of this amount, 64,500 t was used in animal feed additives, automobile body fillers, caulks, joint compounds, paint and putties, sculpture media, tile flooring, and vinyl sheet flooring. The remainder of the "Other" category (10,900 t) was used in applications that were not identified by respondents.

Most of the imported talc listed in table 6 was not included in the domestic end-use data listed in table 3. Of the 270,000 t of imported talc, approximately 15,000 to 20,000 t was processed and exported. As with 1999, the large tonnage increase in imports probably could not be absorbed in current markets, and about 35,000 to 45,000 t was held in inventory. An estimate of the end-use breakdown based on countries of origin, ports of entry, importing companies, and regional end-use patterns is plastics, 85,000 t; paint, 40,000 t; ceramics and refractories, 20,000 t; paper, 15,000 t; cosmetics, 10,000 t; rubber, 10,000 t; and unknown, 30,000 t.

Pyrophyllite.—Domestic consumption of pyrophyllite was essentially unchanged from that of 1999. Pyrophyllite was used, in decreasing order of consumption, in ceramics, refractories, paint, insecticides, plastics, and rubber. Ceramic and refractory uses accounted for more than 70% of domestic pyrophyllite sales.

Prices

Talc prices varied depending on the quality and the degree and method of processing. The unit value of crude talc was estimated to be $26 per metric ton. More than 85% of the crude ore value included in table 1 was estimated because most talc is sold only after crushing and grinding. Following sorting to remove waste, primary crushing, and screening, the unit value of the unmilled talc probably would be on the order of $50 to $60 per ton, free on board (f.o.b.) at the mill. The average reported unit value of processed talc was $116 per ton, unchanged from that of 1999. The average unit values of crude and processed pyrophyllite decreased slightly from those of 1999.

The average free alongside ship (f.a.s.) unit value for exports of unmilled talc was $236 per ton compared with $114 per ton in 1999. Large fluctuations in pricing can be expected for the low tonnages of crude shipped annually [5,000 to 15,000 metric tons per year (t/yr)]. Additionally, several of the small export shipments have unit values ranging from $700 to $3,552 per ton, suggesting that sculpting-grade talc and talc products such as body powders also may have been included in the export data. The unit value for milled talc exports was $212 per ton in 2000 compared with $195 per ton in 1999. The average Customs unit value for imports was $83 per ton for unground talc (unchanged from 1999), $146 per ton for ground talc ($161 per ton in 1999), and $973 per ton for cut or sawed talc ($932 per ton in 1999).

Approximate prices for talc ranged from $87 to $327 per ton (table 4; Industrial Minerals, 2000d). Quoted prices should be used only as a guideline because actual prices depend on the terms of the contract between seller and buyer. Three of the larger talc producers in the United States announced price increases to compensate for increased fuel costs associated with minerals mining and processing. Deteriorating profit margins also were cited as contributing to the price increase for Luzenac America. Price increases of 2% to 4% were announced by Minerals Technologies Inc., the parent company of Barrett's Minerals; 5% to 8% by Luzenac America; and 5% to 8% by Zemex Corp., the parent company of Suzorite Mineral Products Inc. (Industrial Minerals, 2000c; North American Minerals News, 2000). Talc producers in Guangxi Province in China

Digitized by Google

also announced price increases of up to $2 per ton. The producers cite strong demand and declining reserves in several deposits as the reason for the increase (Industrial Minerals, 2000b).

Foreign Trade

Talc exports increased by 5% in tonnage to 154,000 t and by 21% in value to $32.8 million. Canada was the leading importer of U.S. talc, followed by Venezuela (19,000 t), Belgium, Mexico, Japan, and the Republic of Korea (5,450 t) (table 5). Much of the talc exported to Mexico is shipped to U.S. affiliates operating across the Mexican border and is not reported by the U.S. Census Bureau. Total talc exported across the Mexican border in 2000, including shipments to U.S. affiliates, exceeded 50,000 t.

Talc imports reported by the U.S. Census Bureau increased by 30% in tonnage to 270,000 t and by 20% in value to $42.5 million in 2000. As in 1999, the large increase in imports probably could not be absorbed by talc markets. Some of the imported talc was processed and exported. It is likely that some imported talc was processed and stockpiled for future sales. Announced price increases on some of the Chinese talc may have prompted some importers to make larger than normal purchases before the price changes took effect. Canada, China, and Japan supplied 78% of all talc imports (table 6). Most of the talc imported from Japan was likely to have been transshipments from other Southeast Asian countries or from Australia.

Approximately 36% (98,100 t) of talc imported into the United States came through the customs district of New Orleans, LA, almost all of which was unmilled. Of this amount, 89,900 t was imported from China, 8,000 t from Australia, and 236 t from France. The second leading customs district was Houston, TX, with 38,900 t (mainly unmilled talc from China and France), followed by New York, NY, with 34,400 t (mainly milled talc from Japan and Italy); Detroit, MI, with 31,700 t (mainly from Canada); Charleston, SC, with 18,200 t (milled talc mainly from Italy); Duluth, MN, with 13,300 t (milled talc from Canada); and Buffalo, NY, with 10,200 t (milled talc mainly from Canada). The remaining imports were dispersed among the many other customs districts.

World Review

China remained the world's leading producer of talc, followed by the United States, India, Finland, France, and Brazil. The Republic of Korea was the largest producer of pyrophyllite, followed by Japan and Brazil. China, Japan, the Republic of Korea, and the United States produced 61% of the world's talc and pyrophyllite (table 7).

Australia.—WMC Resources Ltd. sold its 50% share of Mondo Minerals Oy to Omya plc. Mondo Minerals was a consolidation of Finnminerals Oy and WMC's Westmin Talc BV. It was operated as a 50-50 joint venture with Omya. WMC still owns the Three Springs talc mine in Western Australia but has decided to sell that operation as well. The company had just inaugurated its new $11 million micronizing mill in October. WMC's Three Springs operation produces micronized talc for the paint, paper, plastics, and technical ceramics markets (Industrial Minerals, 2000e).

Poland.—Rozmin s.r.o. began studying proposals for mine construction at its Gemerska Poloma talc deposit in eastern Slovakia. The company anticipated production to begin in mid-2000 at a rate of 80,000 t/yr. The deposit contains an estimated 16 million metric tons of reserves. Rozmin will jointly market the talc with Gebrueder Dorfner GmbH and Co., a German marketing company. The talc will be sold for paint, paper, plastic, and rubber applications (Industrial Minerals, 2000a).

Outlook

While still strong, sales of talc have declined slightly over the past 2 years. An economy that began slowing in early to mid-2000 has contributed to the decline and does not bode well for 2001. Major markets for talc, such as ceramics, paint, and paper, which were projected to grow through 2003, probably will begin to level off. This mirrors a decline in new housing units being built; new home construction uses many products that contain talc. Plastics still offer the greatest opportunity for expansion. Imports will continue to play a larger role in the U.S. talc market, particularly in the plastics markets. No major changes are anticipated in pyrophyllite markets, and consumption probably will not change significantly for the next few years.

THORIUM

By James B. Hedrick

Domestic survey data and tables were prepared by Jason T. Collins, statistical assistant, and the world production tables were prepared by Ronald L. Hatch, lead international data coordinator.

Thorium is the second member of the actinide series of elements in the periodic table. As a pure metal, it is a soft, very ductile, heavy, silver-gray metallic element. It is represented by the chemical symbol Th and several isotopic symbols, the most common being, thorium-232 (Th^{232}). Thorium metal has a very high melting point at 1,750° C. The oxide, which is also called thoria, has the highest melting point of all the binary oxides at about 3,300° C. Th^{232} is the most abundant of the four naturally occurring isotopes of thorium. Th^{232} emits radioactive alpha particles and has a very long half-life of 1.405×10^{10} years. Daughter products created by the radioactive decay of Th^{232} emit alpha, beta, and gamma emissions. Most products of the disintegration series have short half-lifes, ranging from 5.75 years to 0.145 second. The final decay product of the Th^{232} series is the stable isotope Pb^{208}. Thorium's other naturally occurring isotopes (typically uranium decay products), Th^{228}, Th^{230}, and Th^{234}, have half-lifes of 1.9116 years, 75,380 years, and 24.1 days, respectively.

Thorium was discovered in 1828 by Swedish chemist and mineralogist Jöns Jakob Berzelius (Söderbaum, 1929). He named it "thoria," after Thor, the ancient Norse god of thunder. Berzelius isolated the element from a black silicate mineral from the island of Lövö near Brevig, Norway (Weeks and Leicester, 1968, p. 532). Subsequently, the black mineral from which thoria was derived was named thorite. In 1898, thorium's radioactivity was discovered independently by Marie S. Curie (Curie, 1928) and Gerhard C. Schmidt (Badash, 1966).

At 7.2 parts per million, thorium is the 39th most abundant of the 78 common elements in the Earth's crust. It is about three times more abundant than uranium and is associated with uranium in igneous rock. Because the primary thorium minerals are more resistant to geochemical and physical weathering, the thorium-to-uranium ratio in sedimentary rock is typically higher than its ratio in igneous source rock. Thorium occurs in several minerals, the most common being the rare earth thorium-phosphate mineral monazite, the thorium silicate minerals thorite (Berzelius, 1829) and huttonite (Pabst, 1951), and the hydrated thorium silicate mineral thorogummite (Hidden and Mackintosh, 1889, p. 480-481).

Domestic consumption of refined thorium products decreased substantially in 2000 (table 1). The value of thorium metal and compounds used by the domestic industry was estimated to be about $285,000. Thorium and its compounds were produced primarily from monazite recovered as a byproduct of processing heavy-mineral sands for titanium and zirconium minerals or for tin minerals. Monazite was recovered primarily for its rare-earth content, and only a small portion of the thorium produced was consumed. The major monazite-producing countries were Brazil, India, Malaysia, and Sri Lanka. All thorium compounds, metal, and alloys used by the domestic industry were derived from imports, company stocks, or material previously sold from U.S. Government stocks.

Limited demand for thorium, relative to the rare earths, continued to create a worldwide oversupply of thorium compounds and residues. Most major rare-earth processors have switched feed materials to thorium-free intermediate compounds, such as rare-earth chlorides, nitrates, or hydroxides. Excess thorium not designated for commercial use was either disposed of as a radioactive waste or stored for potential use as a nuclear fuel or other application. Principal nonenergy uses have shifted from refractory applications to welding electrodes, chemical catalysts, and lighting.

Problems associated with thorium's natural radioactivity represented a significant cost to companies involved in its

Thorium in the 20th Century

In 1900, thorium brightened the world by providing light in the form of brilliant white incandescent lamp mantles. Thorium was derived entirely from the mineral monazite, which was mined for both the oxides of the rare earths and the thorium it contained. At the turn of the last century, 412 metric tons of monazite valued at $48,805 were produced in North Carolina. Most of the monazite produced domestically was exported to Germany and Austria for the manufacture of lamp mantles. Domestic demand for thorium-bearing monazite increased in 1900 when the competing deposits in Brazil came under the control of a single group, and the price of thorium increased. The use of thorium in lamp mantle manufacture was its only commercial application at the start of the 20th century and accounted for 92% of its nonfuel use in 1950. Large demand for thorium, however, had started dimming by 1912 as the gas mantle was largely replaced in the home by incandescent electric light.

In 2000, thorium was no longer produced in the United States and most other parts of the world because of concerns about its naturally occurring radioactivity. The real and potential costs related to compliance with State and Federal regulations, proper disposal, legal liability, and monitoring of its radioactivity have severely limited thorium's commercial value. Most major domestic thorium consumers switched to nonradioactive substitutes in the 1990s. Monazite production in the United States ceased at the end of 1994 owing to decreased demand for thorium-containing ores. Principal uses for thorium in 2000 were in welding electrodes, chemical catalysts, high-temperature refractory applications, incandescent lamp mantles, traveling wave tubes, and microwave-emitting magnetron tubes for radar and microwave ovens.

Digitized by Google

mining, processing, manufacture, and use. Increased costs to comply with environmental regulations, to deter potential legal liabilities, and to purchase storage and waste disposal space were the principal deterrents to its commercial use. Concern of the effect of thorium's natural radioactivity on health has not been a significant factor in switching to alternative nonradioactive materials.

Legislation and Government Programs

The National Defense Authorization Act for Fiscal Year 2000 (Public Law 106-65), which was enacted on October 5, 1999, did not change the previous authorization for the disposal of all stocks of thorium nitrate in excess of the National Defense Stockpile (NDS) goal of 272,155 kilograms (kg) (600,000 pounds). The law authorized the transfer of no more than $150 million from the NDS transaction fund to the operation and maintenance accounts (no more than $50 million each) of the Army, Navy, and Air Force (section 304). The law also obligated no more than $78.7 million of the NDS transaction fund for the operation of the NDS program, including disposal of hazardous materials that are environmentally sensitive, which would include thorium.

The Floyd D. Spence National Defense Authorization Act for Fiscal Year 2001 (Public Law 106-398), which was enacted on October 30, 2000, continued the funding of $150 million ($50 million each) of the operation and maintenance accounts of the Army, Navy, and Air Force by the NDS transaction fund. The law obligated no more than $71 million of the NDS transaction fund for the operation of the NDS program, including disposal of hazardous materials that are environmentally sensitive, a decrease of $7.7 million from the previous fiscal year. The revised annual material plan for fiscal year 2000 authorized the disposal of 2,946,033 kg (6,494,891 pounds) of thorium nitrate from the NDS classified as excess to goal.

Production

Domestic mine production data for thorium-bearing minerals were developed by the U.S. Geological Survey from a voluntary survey of U.S. thorium operations. The survey form was sent to one mine, the only previously producing thorium-bearing monazite mine still in operation and it responded. Although thorium was not produced in the United States in 2000, the mine that had previously produced thorium-bearing monazite continued to operate and maintained capacity on standby. Monazite was last produced in the United States in 1994.

Essentially all thorium alloys and compounds used by the domestic industry were derived from imports, company stocks, or materials sold from the NDS. Domestic companies processed or fabricated various forms of thorium for nonenergy uses, such as lighting, chemical catalysts, and welding electrodes.

Consumption

Statistics on domestic thorium consumption were developed by surveying various processors and manufacturers, evaluating import-export data, and analyzing Government stockpile shipments.

Domestic thorium producers reported consumption of 6 metric tons (t) of thorium oxide equivalent in 2000, a decrease from the 7 t consumed in 1999 (table 1). Nonenergy uses accounted for almost all domestic consumption.

Because of the high melting point of thorium oxide it was used in several refractory applications. High-temperature uses were in ceramic parts, investment molds, and crucibles.

Thorium nitrate was used overseas in the manufacture of lamp mantles for use in incandescent camping lanterns, and natural gas and oil lamps. Thorium mantles provide an intense white light that can be adjusted towards the yellow region by the addition of a small amount of cerium. Thoriated mantles have not been produced domestically since the development of a suitable thorium-free substitute, a proprietary yttrium-based mixture.

Thorium nitrate was also used to produce thoriated tungsten welding electrodes. These electrodes were used to join stainless steels, nickel alloys, and other alloys requiring a continuous and stable arc to achieve precision welds.

The nitrate form was also used to produce thoriated tungsten elements used in the negative poles (cathodes) of magnetron tubes and traveling wave tubes, also known as TWTs. Thorium was used because of its ability to emit free electrons at ambient temperatures when heated in a vacuum. With an improved work function and lower operating temperature, thoriated cathodes lasted longer than nonthoriated filaments. Magnetron tubes were used microwave ovens and to emit electrons at microwave frequencies in radar systems for air traffic control, surveillance, weather monitoring, and weapon systems.

Other applications of thorium included chemical catalysts, electron-emitting tubes, special-use light bulbs, fuel cells, high-refractivity glass, photoconductive films, radiation detectors, and target materials for x-ray tubes.

In metallurgical applications, thorium had been used as an alloy with other metals, primarily magnesium. Magnesium-thorium alloys were used by the aerospace industry for their lightweight, high strength, and excellent creep resistance at elevated temperatures. Thorium-free magnesium alloys with similar properties have been developed and have replaced most of the thorium-magnesium alloys. Small quantities of thorium were used in dispersion-hardened alloys for high-strength, high-temperature applications, because thorium metal has a high melting temperature of 1,750° C and a boiling point of about 4,790° C.

Thorium was used as a nuclear fuel in the Th^{232}/U^{233} fuel cycle. No foreign or domestic commercial reactors were operating with this fuel cycle; however, thorium was being tested as a fuel component in Russia.

Stocks

Government stocks of thorium nitrate in the NDS were 3,218,177 kg (7,094,865 pounds) on December 31, 2000. The NDS inventory included 273,181 kg (602,262 pounds) of containerized thorium nitrate allocated to meet the NDS goal requirements and 2,944,995 kg (6,492,603 pounds) classified as excess to the goal. No stocks of thorium nitrate were sold or shipped during the year, the NDS, however, received additional stocks of 1,349 kg (2,974 pounds) of thorium nitrate.

The U.S. Department of Energy (DOE) inventory at yearend

Digitized by Google

2000 was 182,000 kg of thorium oxide equivalent contained in metal and various compounds. The DOE contractor, Fernald Environmental Restoration Management Co., which is a division of the Fluor Corp. subsidiary Fluor Daniel Inc., shipped 353 t of thorium oxide to Nevada for disposal during the year.

Prices

The price of monazite concentrate (typically sold with a minimum 55% rare-earth oxide content, including thorium oxide), free-on-board (f.o.b.) as quoted in U.S. dollars and based on 1997 U.S. import data, remained unchanged at $400.00 per metric ton. In 2000, no monazite was imported into the United States.

Thorium oxide prices in 2000, quoted by Rhodia, Inc., were unchanged from the previous year's level. At yearend, thorium oxide prices per kilogram f.o.b. Shelton, CT, were $82.50 for 99.9% purity and $107.25 per kilogram for 99.99% purity. Thorium nitrate prices from Rhodia were $27.00 per kilogram for mantle-grade material.

World Review

Thorium demand continued to remain depressed as industrial consumers expressed concerns about the potential liabilities, the cost of complying with environmental monitoring and regulations, and the cost increases at approved waste disposal sites.

Current Research and Technology

Radkowsky Thorium Power Corp. (RTPC) received its fourth and final U.S. patent for its nonproliferative seed-and-blanket fuel assembly. The patent was issued to inventor Alvin Radkowsky and the assignee, RTPC. The invention details an improved seed-blanket reactor, which can provide optimum operation from an economic and a nonproliferative perspective. An additional objective is to provide a reactor design that uses large quantities of plutonium and thorium without generating proliferative waste byproducts (U.S. patent No. 6,026,136, issued February 15, 2000).

In July, the Kurchatov Institute obtained a license from the Russian Nuclear Regulatory Committee to begin testing the Radkowsky-designed thorium fuel. An additional 35 scientists at the Kurchatov Institute in Russia were assigned to work with the Radkowsky thorium fuel team. Fuel irradiation experiments began by testing the thorium fuel ampoules in an IR-8 reactor (Thorium Power, July 2000, Thorium power—2000, accessed January 5, 2001, at URL http://www.thoriumpower.com/whats_new/2000.html).

Outlook

Thorium's use in the United States has decreased substantially during the past decade. Domestic demand is forecast to remain at 2000 depressed levels unless low-cost technology is developed to dispose of residues or its use as a nonproliferative nuclear fuel gains widespread commercialization. Its future use in nonenergy applications is expected to continue as a chemical catalyst. Manufacturers have successfully developed acceptable substitutes for thorium-containing incandescent lamp mantles, paint and coating evaporation materials, magnesium alloys, ceramics, and investment molds. The traditionally small markets for domestic thorium compounds, chemical catalysts, welding electrodes, and lighting are expected to remain the leading consumers of thorium compounds through the next decade and longer.

The potential for growth in the applications of thorium in nonenergy applications is limited by its natural radioactivity. Its greatest potential exists in energy applications as a nuclear or a subatomic fuel in industries that accept radioactivity. In the long term, however, high disposal costs, increasingly stringent regulations, and public concerns related to thorium's natural radioactivity are expected to continue to depress its future use in nonenergy applications, especially in the United States.

TIN

By James F. Carlin, Jr.

Domestic survey data and tables were prepared by Elsie D. Isaac, statistical assistant, and the world production tables were prepared by Linder Roberts, international data coordinator.

Tin was not mined in the United States during 2000. Twenty-five firms consumed 86% of reported primary tin used domestically. The major uses were as follows: electrical, 24%; cans and containers, 21%; transportation, 14%; construction, 11%; and others, 30%. The estimated value of primary metal consumed domestically was about $310 million. Industry stocks remained steady (tables 2 and 4).

About 17,600 metric tons (t) of tin in old and new scrap, including tin alloys, were recycled (table 5); of this about 6,600 t was old scrap. Almost one-fifth of the tin consumed in the United States was produced at 4 detinning plants and 45 secondary nonferrous-metal processing plants. Interest remained strong in the recycling of used tin cans, partly because of rising fees and limited space at landfills. The recycling rate for steel cans was 58% in 2000, compared with 58% in 1999, 56% in 1995, and 15% in 1988.

The Defense Logistics Agency (DLA), which manages the National Defense Stockpile (NDS), sold 12,000 t of pig tin from the stockpile during 2000. At yearend, 59,686 t remained in the stockpile.

World tin mine output increased by 10% (tables 1 and 9). Industry observers believed that world supply and demand were in approximate equilibrium. World tin smelter production increased by 2%. The average Platt's Metals Week composite price for tin rose by 1%.

Of the 22 countries in which tin was mined, the top 6 accounted for 91% of the world total of 238,000 t. China was the largest producer (41% of the world total) and was followed by Indonesia (20%), Peru (16%), Brazil (5%), Bolivia (5%), and Australia (4%) (table 9).

World tin reserves, estimated to be 8 million metric tons (Mt), were considered to be adequate to meet the world's future tin requirements. Assuming that world primary tin consumption will be about 200,000 metric tons per year (t/yr), these reserves would last 38 years. Most tin reserves are in Asia and South America.

Legislation and Government Programs

In 2000, the DLA sold 12,000 t of pig tin in the NDS to two companies. Both sales were long-term contracts allowing for deliveries of the tin over a 1-year period. Spot market sales of tin ended in 1999. The effect of NDS tin sales on domestic markets is assessed by the Market Impact Committee, composed of several Federal Agencies, including the U.S. Geological Survey (USGS). The NDS tin is stored at Government sites in Hammond, IN; Baton Rouge, LA; Point Pleasant, WV; and New Haven, IN. At yearend, the remaining unsold inventory was 59,686 t.

Production

Mine.—Tin was not produced at any U.S. mine in 2000. Until 1993, a few small tin mines had operated sporadically in the United States for many years. However, USGS canvasses confirm that there has been no domestic tin production since that year.

Secondary.—Industry observers believe the United States is the world's largest producer of secondary tin. Most secondary

Tin in the 20th Century

In 1900, the United States was the world's major tin user. Domestic tin production was modest and came mostly from Alaska. The Nation depended almost entirely on tin imports for its needs. Over 80% of the tin imported came from Malaysia, which was the world's dominant tin producer at the time. Statistics are not available, but there is evidence that solder and tinplate were the major domestic uses for tin, with bronze and tinning next in importance. In 1900, all tinplate was made by the hot-dip process on cut-length sheets. The electrolytic tinplate process was developed in Germany in the late 1930s, under the impetus of accelerated production needed for Germany's war effort. By the early 1940s, the high-speed electrolytic process took hold in the United States, and by the mid-1960s hot-dipping was phased out. In 1939, tin became the first material purchased for a U.S. Government stockpile established for wartime use. From the late 1940s through the early 1950s, acquisitions of tin for the Government stockpile surged and reached a peak of about 500,000 metric tons. In 1959, Congress approved tin sales from the Government stockpile. Tin was the first material to be sold from the stockpile (1960) and was offered for sale almost continuously up to the end of the century when sales had reduced tin stockpile inventories to 60,000 tons. Since establishment of the Government stockpile in 1939, tin has almost always had the highest inventory value in the stockpile.

In 2000, the United States had no domestic tin mine or smelter production. The country was dependent mostly on imports for its tin needs. Peru was the major supplier, followed by China, Bolivia, Brazil, and Indonesia. The United States remained the world's largest user of tin. Solder was the dominant market for tin consumption domestically, followed by tinplate, chemicals, and brass/bronze. The use of tin for tinplate had declined sharply since 1960 due to competition in the beverage container sector from materials like aluminum and plastics. Tin chemicals represented a somewhat new market essentially starting in the early 1950s

Digitized by Google

tin was produced from various scrapped alloys of tin and recycled in those same alloy industries. In 2000, however, tin metal recovered from new tinplate scrap and used tin cans was the only type of secondary tin available in the marketplace as free tin. Secondary tin from recycled fabricated parts was used in many kinds of products and was particularly important for the manufacture of solder and brass/bronze.

The former Steel Can Recycling Institute, created in 1988 and funded by five domestic tinplate producers to advance the collection, preparation, and transportation of steel can scrap, was in its sixth full year of expanded activities in 2000 under its new name, The Steel Recycling Institute (SRI). The SRI fostered the collection of all steel scrap (ranging from appliances to cars), not just steel cans. Its representatives in various regions of the United States continued to work with municipalities, scrap dealers, and detinners to promote the recycling of tin cans. The SRI announced that the recycling rate for steel cans, most of which are made from tinplate, remained at about the same rate (58%) as in 1999 (Steel Recycling Institute, 2001).

APEAL, a Belgium-based organization of European packaging firms that use considerable amounts of tinplate, released 1999 data on the recycling of steel packaging in Europe. The data indicated a marked increase in recycling rates for most countries in the European Union (EU). The overall rate for recycling was 46%. Germany ranked first with an 80% recycling rate, mostly due to its selective, multimaterial collection system. Integral collection and magnetic separation prior to incineration still account for over one-half of recycled steel packaging in the EU, but the more recent introduction of curbside collections and recycling banks has been so successful that APEAL considers the combined approach as essential (Metal Bulletin Monthly, 2000b).

Consumption

In 2000, domestic consumption of primary tin remained almost identical to that of 1999. Secondary consumption increased slightly. Domestic consumption data for tin were developed by the USGS from a voluntary survey of tin consumers. Of the 149 firms to which a survey form was sent, 125 responded, for an 84% response rate (table 3).

In 2000, tinplated steel and tin-free cans accounted for 23% of the 136 billion metal cans shipped domestically; aluminum cans accounted for the remainder. The proportions were the same as in 1999. Steel tinplate dominated in the food, pet, and the "general line" can markets, and aluminum held 100% of the beverage can market (Can Manufacturer's Institute, 2001).

The U.S. Steel Group of USX Corp. (Pittsburgh, PA) announced late in the year that it would acquire the tin mill products business of LTV Corp. (Cleveland, OH); the acquisition was completed early in 2001. The tin mill products operations that were acquired are in Aliquippa, PA, and East Chicago, IN. Upon takeover, U.S. Steel shutdown the Aliquippa facility. Under the terms of agreement with LTV, U.S. Steel assumed about $95 million of LTV's employee related obligations, including shutdown benefits for about 400 workers at the tin mill in Aliquippa, PA, and the assumption of pension, medical, and life insurance obligations for all employees. About one-half of the expense was covered by U.S. Steel's overfunded pension plan. The LTV purchase made U.S. Steel Corp. the Nation's major producer of tin mill products. In acquiring LTV's 500-employee tin mill at its large Indiana Harbor Works in East Chicago, IN, U.S. Steel boosted its capacity to produce tin-coated sheet to about 1.7 million metric tons per year (Mt/yr). U.S. Steel tin mills at its large Gary, IN, works and at its smaller Fairless Works (Fairless Hills, PA) together can produce about 1.3 Mt/yr. The domestic tinplate market is estimated to be about 4.5 Mt/yr (American Metal Market, 2000).

Weirton Steel Corp. (Weirton, WV) announced that it will enter the coated coil industry when it begins a new polymer film coating line during the first half of 2001. The planned line will have the capacity to apply a thin coat of polymer film on 200,000 t/yr of tinplated steel. Several sites for the facility are being considered. The polymer coating process is a new technology that reportedly is superior to conventional lacquer coating systems. Polymer-coated tinplate is used for the top and bottom lids of food containers, aerosol cans, and other containers. Weirton has been the largest U.S. tinplate producer for many years and is the eighth largest domestic integrated steel company (Weirton Steel Corp., 2000).

Prices

The Platt's Metals Week average composite price for tin metal rose by 1% during 2000 compared with that of 1999. The Platt's Metals Week average commodity price was $3.98 per pound in January, its highest monthly level all year. And, it ended the year at $3.59 per pound, in December, its lowest monthly level all year.

The London Metal Exchange (LME) remained the primary trading arena for tin. Tin was one of only six metals to be traded on the LME; the other metals included aluminum, copper, lead, nickel, and zinc. The LME announced the start of trading on its new LMEX contract on April 10. LMEX is a futures-based weighted index contract covering the six primary nonferrous metals traded on the LME. The new index uses a base of 1,000 points calculated from January 4, 1999. At the end of the first day's trading, the index stood at 1,270 points. LMEX is designed to attract the institutional investor by spreading liquidity across all the metals and thus reducing volatility in each metal contract. Initially, LMEX had 15 of the 40 LME member firms involved in the new contract. Other firms are expected to follow (Tin International, 2000b).

The LME announced that it was considering the storage of tin in Singapore. In the past, Singapore had been ruled out for such tin storage because it is near sizable production facilities, and the LME's policy has been to site delivery points in areas of net consumption (Platt's Metals Week, 2000c).

The Kuala Lumpur Tin Market (KLTM) announced that it had received the needed approvals for trading its tin contracts in United States dollars. Its board subsequently decided to change contract pricing from the Malaysian ringgit to the dollar starting on February 2, 2001. The KLTM was established in 1984 as a physical market to provide facilities for buying and selling tin and for the daily determination of tin prices. Its contract calls for trading tin on warrants for prompt delivery, within four business days, of the following brands: MSC (Malaysia), Thaisarco (Thailand), and Bangka and Mentok (both Indonesia).

Digitized by Google

The KLTM daily price quotation has been traditionally used as a reference price for contract pricing for producers and consumers in the Asia-Pacific region, which produces over 80% of the world's tin. Along with the change to a dollar contract, the KLTM board also decided to introduce electronic daily trading to replace the current pit system of daily price setting. This new system is to be implemented by June 2001 (Tin International, 2000b).

Trade

U.S. imports of refined tin, which supplied most domestic tin requirements, decreased by 5% in 2000. Imports of tin in all forms (ore and concentrate, metal, waste, and scrap) remained duty free (tables 7 and 8). In the United States, trading firms marketed most of the tin metal imported from a variety of countries and then warehoused in this country until sold to customers. Foreign-owned trading firms tended to dominate the domestic field.

Imports of refined tin to the United States were dominated by China and Peru. Bolivia, Brazil, and Indonesia ranked next in importance. Tin exports were small compared with imports (table 6).

After the U.S. Department of Commerce assessed antidumping duties of over 95% against four Japanese tinplate producers, based on an investigation covering a period from October 1, 1998, through September 30, 1999, the U.S. International Trade Commission (ITC) imposed a 95% antidumping duty on most tinplate imports from Japan. The final affirmative injury determination drew a strong negative response from Japanese tin mill owners because the ITC found injury in a case that had only one domestic tin mill petitioner, Weirton Steel Corp., Weirton, WV. Weirton, the only one of seven major U.S. tinplate producers to file the antidumping petition, claimed that the ITC ruling was crucial for the company's long-term viability. Weirton has been the largest U.S. tinplate producer for many years, with a 22% market share. The ITC's 95% duty will apply to imports from Kawasaki Steel Corp., Nippon Steel Corp., NKK Corp., and Toyo Kohan Corp., the major Japanese tinplate exporters. The United States imported about 337,000 t of tinplate from Japan in 1999, up from an average of about 210,000 t/yr in the prior 3 years (Metal Bulletin, 2000h).

World Review

Argentina.—Sunshine Mining and Refining Co. (USA) announced that it is still attempting to find sources of funding to develop its Pirquitas silver-tin-zinc mine in Argentina. The company has had an operating permit since 1999 but has been frustrated by financing problems arising from the low price of silver. Sunshine, primarily a silver miner, originally bought the mine in 1995 for $1.7 million. The property had been mined for many years by local operators who went into liquidation in 1990. Sunshine has since invested $20 million in the project (Tin International, 2000b).

The country's only tinplate producer, Siderar SAIC, returned its only tinning line to production following modernization by Techint Technologies Co. (Pittsburgh, PA). The line's speed was increased from 244 meters per minute to 305 meters per minute. The line's capacity is now 150,000 t/yr compared with a previous 120,000 t/yr. Siderar's tinning line produces mainly for domestic markets (Metal Bulletin, 2000f).

Australia.—Murchison United NL announced an agreement with the Tasmanian State Government to jointly fund a $22 million, 6-year exploration and development program aimed at securing the long-term future of the company's Renison Bell tin mine. This new program will enhance a prior $13 million program already underway at Renison designed to convert existing inferred resources to reserves and extend mine life beyond 10 years. Murchison acquired Renison in 1998 and has since been transforming it into one of the world's lowest-cost tin mines.

Marlborough Resources NL Group announced that it had reached an agreement to acquire a subsidiary of Western Metals Ltd., which owns the defunct Ardlethan tin mine, for an agreed purchase price of $1. Marlborough will take responsibility for rehabilitation of the old tin project, which was closed down in 1986. Tailings dams at the site contain about 8 Mt of tailings with a grade of about 0.19% tin. Thus, about 15,000 t of tin are contained in the tailings, which have a current in-situ value of about $90 million. Marlborough has conducted several detailed studies of these tailings over the past 20 years and believes that recoveries of between 55% to 65% may be possible depending on the process used. The firm also will be conducting further test work on the site to determine the most economical process and equipment to maximize profitability from the treatment of tailings. The firm plans to transport the retreated tailings back into the original open cut. In addition to the tailings, there are significant alluvial tin resources on some of the 53 mineral tenements included with the acquisition (Tin International, 2000e).

Phelps Dodge Corp. (USA) announced that it agreed to join the Australian company, Platsearch Ltd., in its Tara copper-zinc-tin exploration project in New South Wales. Under the terms of the agreement, Phelps Dodge can earn a 60% stake in Tara by spending $1.2 million on a ground magnetic survey and a 400-meter drill hole. Once Phelps Dodge has earned its 60%, Platsearch and its existing partner, Nosebi Mining and Management, will participate at 32% and 8%, respectively. Previous drilling at Tara intersected narrow widths of copper-zinc-tin mineralization. Phelps Dodge planned to begin drilling in 2000 (Platt's Metals Week, 2000e).

Bolivia.—The ownership of the Vinto tin smelter and the Huanuni tin mine completely transferred to Allied Deals Corp. Allied paid $15 million for the smelter and associated assets and also paid $500,000 for a 30-year lease on what may be the world's largest underground tin mine. Vinto produces about 11,000 t/yr of low-lead tin. Allied plans to increase production at Vinto to 15,000 t/yr in 2001-2002 and then to further increase output to 18,000 to 20,000 t/yr in 2 more years. Also, new sources of tin concentrate would be sought; Vinto's feedstock now comes from Bolivia and Brazil (Platt's Metals Week, 2000g).

Brazil.—The country's largest steelmaker, Compañia Siderúrgica Nacional (CSN), announced that it was seeking contractors to modernize the company's no. 3 and no. 5 electrolytic tinning lines at its Volta Redonda Works. Work is expected to start in January 2001 on the $150 million modernization. The upgrade will allow CSN to produce thinner

Digitized by Google

and more sophisticated grades of tinplate, including double-reduced grades as well as drawing and ironing grades for two-piece beverage cans. CSN has six tinning lines at Volta Redonda with a combined capacity of 1.1 Mt/yr of tinplate. CSN is the world's fifth largest tinplate producer and the largest on a single site. About 70% of CSN's tinplate output is used domestically and 30% is exported (Metal Bulletin, 2000b).

Chile.—The largest Chilean steel producer, Compañia Siderúrgica Huachipato (CSH), a subsidiary of Chile's Cap Group, celebrated its 50th anniversary. CSH is Chile's only integrated steelmaker. Located along the San Vicente Bay in southern Chile, the plant employs almost 3,000 workers and has the capacity to produce 1.2 Mt/yr of steel. Among its several finishing mills is a tin mill with a Ferrostan electrolytic tinning line that has an annual capacity of 100,000 t (Metal Bulletin Monthly, 2000a).

China.—The Government of China, the world's largest tin producer, announced that it will seek to attract foreign investment for mining in Xinjiang Province, in northwestern China. The Government intends to adopt preferential policies to attract foreign capital to tap vast resources of natural gas, coal, and nonferrous metals in Xinjiang along with state-owned mining enterprises. Foreign companies that invest in Xinjiang will be eligible for exemption from fees for mining rights in the first year and a subsequent 50% reduction for the next 2 years. Wholly owned foreign companies and joint ventures will be exempt from mineral resource compensation fees for 5 years. Also, the Government will seek to attract investment by issuing stocks, holding assets sales, and franchising. China believes these moves would accelerate its entry into the World Trade Organization and further lift its economy. Geologists working in Xinjiang recently discovered deposits of copper, nickel, lead, zinc, and tin near the province of Urumqi, an estimated total of about 1.2 Mt of base metal ores in an area covering almost 860,000 square kilometers (Metal Bulletin, 2000a).

The country's major tin producer, Yunnan Tin Corp., announced that it expected a delay in the completion of its new furnace, citing technical difficulties. Officials projected a late 2001 startup. Yunnan is upgrading its 24,000 t/yr tin smelter in Gejiu City by replacing several reverberatory furnaces with a new furnace. The furnace will continue to process 50,000 t/yr of concentrate and produce 24,000 t/yr of refined ingot. Yunnan has invested $12 million in the upgrade. In 2000, Yunnan continued to target a maximum output of 24,000 t of refined tin, which is in-line with 1999 production (Platt's Metals Week, 2000h).

Denmark.—The Government announced plans to impose a wide-ranging ban on the use of lead. It would be the first country to do so. The ban becomes effective March 1, 2001, and will affect the use of lead and lead compounds in the construction and electronics industry, use of lead as a stabilizer in plastics, and use of metallic lead in ballasts and weights. The ban has implications for tin because tin is often used as a replacement for lead in such applications (Mining Journal, 2000b).

Germany.—The Government was considering extending its deposit system for used beverage containers to include disposable steel (tinplate) and aluminum cans. According to the deposit proposal, a fee of 50 pfennigs (49 cents) would be imposed on each disposable can as well as on glass and plastics bottles. The deposit would be refunded when the container is returned. Glass or plastic bottles already carry a deposit of between 15 and 70 pfennigs each. All other beverage packaging currently is discarded, although much of it enters the recycling chain. In Germany, over 90% of cans are made from steel, amounting to roughly 170,000 t of tinplate. Recycling of tinplate is now at about 80% in Germany, the highest rate in Europe (American Metal Market, 2001).

The country's only tinplate producer, Rasselstein Hoesch GmbH (RHG), owned by ThyssenKrupp AS announced plans to shutter one of its plants in an attempt to bolster profitability. The plant to be closed is RHG's Dortmund facility, with a tinplate capacity of 180,000 t/yr. Its closure is set for three stages, with operations to cease completely by the end of 2001. RHG has its main plant in Andernach, with tinplate capacity of 900,000 t/yr. Its capacity is to be expanded to 1 Mt/yr by the end of 2001 (Tin International, 2000f).

Indonesia.—PT Timah, the country's largest tin producer, announced an anticipated decline of 12% in its refined tin output during 2000. The company attributed lower output to predicted poor weather and declining resources. Timah is still attempting to resolve long-standing land ownership issues with local inhabitants on the islands of Bangka and Belitung, the sites of most of its tin mining and smelting. Timah acknowledged that additional uncertainty looms as the Indonesian Government appears set to declare Bangka Island as a province, possibly giving local authorities autonomous powers. If that becomes a reality, the company may be forced to pay separate royalties to the local Bangka provincial administration. Timah is currently seeking opportunities to expand its tin operations into Burma, Cambodia, and Vietnam (Metal Bulletin, 2000d).

The Government announced that it has granted PT Koba Tin a 10-year extension of its contract to operate in Indonesia. Koba Tin is 75% owned by Iluka Resources NL (Australia). Koba has been mining tin at a rate of 10,000 t/yr (Platt's Metals Week, 2000b).

Herald Resources Ltd. (Australia) announced the discovery of significant tin mineralization during a drilling program at is Batu Besi property on Belitung Island. Tin values in the range of 1.2% have been reported. The island has long been home to major tin mining operations of PT Tambang Timah (Mining Journal, 2001a).

Japan.—The country's tinplate industry finds itself in an acutely competitive market. Over the past 4 years, consumption of beverages in tinplate cans has fallen as part of an overall decrease in the consumption of canned beverages in Japan. The tinplate makers are facing greater competition from popular, portable half-liter plastic bottles that have garnered a growing share of the packaging market for carbonated and noncarbonated beverages. In 1999, about 35 billion cans made of tinplate, tin-free steel (TFS), and aluminum were used in Japan. This total represent an 8% decline in can consumption compared with about 38 billion cans used in1998, and a 13% decline compared to the 40 billion cans used in 1996. Steel cans are estimated to account for about 60% of all cans used in Japan; of these, tinplate and low-tin cans represent 35%, while TFS cans account for the remaining 25% share; aluminum cans represent the other 40% share of the can market.

In 1999, Kawasaki Steel Corp. produced 25,000 metric tons

Digitized by Google

per month (t/mo) of tinplate a month for local sale and export; about 11,000 t/mo of TFS was produced for local and overseas sale. Kawasaki's output included a low-tin coated steel designed for making three-piece cans. In the production process, an iron-nickel-tin alloy layer is formed by electrotinplating and a flow melting process. The low-tin product accounts for 25% of the firm's tinplate output. Most of the product is supplied to Japanese canmakers to make beverage cans for coffee and sports drinks.

In 1999, Kawasaki exported a total of 170,000 t of tinplate. One-half of the firm's tinplate exports are shipped to the United States, while other big markets are China, Indonesia, and the Philippines. Until recently, Japanese steel mills supplied about 350,000 t/yr of tinplate to the United States, accounting for almost 10% of the U.S. tinplate market. In 1999, Kawasaki supplied 88,000 t of tinplate to U.S. customers, representing 25% of total Japanese tinplate exports to the United States (Tin International, 2000a).

Korea, Republic of.—This country, with four tinplate producers, has become a major force in the tinplate market during the past decade. The Republic of Korea's tinplate consumption is estimated at 385,000 t/yr, and imports account for about 25,000 t of that total. Pohang Iron and Steel Corp. (POSCO) was the country's leading domestic tinplate market supplier with an estimated 31% market share in 1999, representing tinplate sales of 110,000 t/yr. The second largest local supplier was Dongbu Steel Corp. with sales of 96,000 t in 1999, or about a 27% market share. In third place was Dongyang Corp. with an estimated 26% domestic market share, or 92,000 t of sales. Shinwha Corp. was in fourth place with sales of 57,000 t and a 16% local market share. Both Dongbu and Dongyang have a larger tinplate manufacturing capacity than POSCO but rely on exports for about one-half their sales. Export orders are important to all four tinplate makers. In 1999, Dongbu and Dongyang were expected to ship export orders far exceeding their domestic sales, while POSCO and Shinwha were expected to supply about one-half of their output to domestic customers. The Republic of Korea's total tinplate-making capacity is about 850,000 t/yr, almost one-half of which is used for export purposes.

Dongbu overtook Dongyang as the Republic of Korea's largest tinplate producer with the startup of its Asan Bay electrolytic tinning line that has a top speed of 650 meters per minute. Dongbu is now able to produce 280,000 t/yr of tinplate; Shinwa produces 90,000 t/yr. The other producer, POSCO, ranks as one of the world's major steel companies and has an annual production of 770,000 t of blackplate substrate. In addition to supplying the domestic market, POSCO exports about 75,000 t/yr. POSCO's main tinplate markets are India and Southeast Asia (Tin International, 2000e).

Malaysia.—The long, narrow, and highly productive Southeast Asian Tin Belt extends over the entire length of the Malay peninsula. It includes parts of Burma and Thailand to the north as well as Malaysia and some western Indonesian islands to the south. The Malaysian portion of the Tin Belt contains about 40% "acid intrusives," presumably granite, mostly in three very long, irregular intrusive zones. These zones generally parallel the north-south trend of the peninsula. The largest of the three, in west-central Malaysia, extends into Thailand. It resembles the Sierra Nevada, CA, and the adjacent Coast Range, British Columbia, Canada, intrusive belts in Western North America. Host rock for the Malaysian intrusive is mostly Paleozoic sedimentary rock with minor volcanics. Malaysian bedrock tin deposits are presumed to be closely associated with a small Permian-to-Triassic-age granite center within the three much larger regional granite masses.

Most of Malaysia's tin mines are in the States of Perak and Selangor. In an attempt to revitalize the tin industry, officials in Perak issued mining licences during 2000. However, Government assistance to find and develop tin prospects reportedly has been lacking in recent years. In 1989, the Government requested the United Nations (UN) to study the situation and make recommendations. In 1991, a UN report was submitted, and the Malaysian Federal Parliament took legislative and regulatory actions in response. Because Malaysian States have autonomy over mining matters, however, the Federal initiatives must await acceptance by the States. Selangor and Sebah States have already accepted the initiatives. The belief is that sufficient resources are available. Presumably, all that is needed to return Malaysia to prominence in tin mining is increased Government support for investment, exploration, and development in the mining sector (Engineering and Mining Journal, 2000).

The Chamber of Mines announced that there were 45 active tin mines in the country in October 1999, 15% more than the 39 mines active in January 1999. Despite this, tin mine output has remained about the same (Platt's Metals Week, 2000d).

Nigeria.—Malaysia Mining Corp. (MMC) was reportedly close to signing an agreement with the Nigerian Mining Corp. (NMC). NMC is a Government-owned entity that holds the leases to most mining rights in the country and manages controlling shares in Consolidated Tin Mines Ltd. NMC officials acknowledged that Nigeria's tin properties require fresh investment and new technologies. MMC has been seeking new opportunities to invest in tin and other metal operations outside Malaysia and further utilize its lengthy mining experience (Metal Bulletin, 2001).

Peru.—The country's major tin miner, Minsur, announced plans to invest $7 million this year in exploration work. During 1999, Minsur completed an expansion at its mine, increasing the production rate from 1,500 metric tons per day (t/d) of tin ore to 2,500 t/d. As a result, the company expects to produce about 3,500 t/yr of tin-in-concentrate. Minsur's Funsur tin smelter production is expected to reach 22,000 t of tin metal in 2000, compared with 18,000 t in 1999.

Russia.—The country's only tin smelter, the Novosibirsk Tin Combine, announced plans to increase output by more than 50% over that of 1999. The firm expected to produce 6,000 t of refined tin and 3,000 t of solder. It also plans to raise total annual output to 20,000 t in 2001, a level not achieved since 1986, to meet increased domestic demand. Novosibirsk plans to move ahead with the development of its resource base in 2001 by making acquisitions and increasing production of tin concentrate at the four mining complexes that it controls or partially owns. By yearend 2000, the four complexes in which Novosibirsk owns an interest were expected to achieve a production level that will cover at least 80% of the smelter's needs, with the Deputakskolovo Tin Mine providing one-half of the total. The firm started a long-term investment program at Deputakskolovo with a total cost of about $5 million. The aim

Digitized by Google

is to increase mine output there by 30% to 40%. The mine is in far eastern Russia at Yakutia and is ice-bound for much of the year (Tin International, 2000d).

Slovakia.—Shareholders in the Slovak steel group, VSZ a.s, approved a plan which would allow U.S. Steel Group to acquire the company's core assets, including its tinplate operations. The deal would add about 3.4 Mt of crude steel production to U.S. Steel's existing 11 Mt. About 84% of VSZ's stockholders gave their support to the proposal as stated in a memorandum of understanding. Officials indicated that U.S. Steel had committed $700 million in capital spending for the first phase of a VSZ modernization program. Initially, the company will complete the upgrade of its current 50-50 tinplate joint venture with VSZ by installing a 200,000-t/yr continuous annealing line. A $26 million temper line will also be installed, followed by a new 200,000-t/yr tinning line. Upon completion of the acquisition, U.S. Steel would target sales primarily within Central and Eastern European markets. U.S. Steel officials believe that markets within 600 kilometers (km) of the Kosice plant location are sufficient to absorb expected mill capacity (Metal Bulletin, 2000g).

Thailand.—The Department of Mineral Resources reported that Thai tin-in-concentrate production increased 69% to 2,700 t in 1999 compared with 1,600 t in 1998. Officials attributed the rise mostly to the increased number of active mines in 1999 (30 compared with 23 mines in 1998). Thailand has only one tin smelter, Thaisarco, which has a maximum output capacity of 36,000 t/yr of refined tin metal. Thaisarco produced 17,000 t of tin metal in 1999, an 11% increase over the 15,000 t produced in 1998. Thailand's tin metal exports were 13,000 t in 1999, compared with 11,000 t in 1998. Domestic tin sales increased 20% in 1999 to 4,800 t (Platt's Metals Week, 2000f).

Turkey.—The country's only tinplate producer, Erdemir, announced that it had increased tinplate output at its Eregli Works from 100,000 to 300,000 t/yr. The increase followed the recent addition of a new tinning line, an electrolytic cleaning line, and a shearing line (Metal Bulletin, 2000c).

United Kingdom.—A proposal was made to reopen the South Crofty Tin Mine by Baseresult plc, a local Cornwall firm. South Crofty was England's last operating tin mine when it closed in 1998. Baseresult was negotiating with South Crofty plc (the mine's owner) for the mine, land comprising the mine-site, and processing equipment from the Wheal Jane concentrator plant nearby. South Crofty's mining permit was extended to allow the negotiations to continue. Baseresult plans to produce 2,000 t/yr of tin-in-concentrate at an operating cost of $2,800 per metric ton of tin, well below the current cost $5,510 per metric ton. However, officials believe the mine can be profitable only if the company diversifies the operation to include other activities (such as waste management from energy facilities in the region). Nevertheless, officials expressed confidence that Baseresult can extend the life of the mine beyond the 7 years during which its plans to mine the upper levels of the deposit (Platt's Metals Week, 2000a).

In Yorkshire, Rio Tinto Ltd. announced that it expected to disprove in court allegations that its former Capper Pass Tin Smelter caused injuries or illnesses among workers and local residents. Rio Tinto's subsidiary, Capper Pass and Son Ltd., located in Hull, was the world's largest tin smelter at the time of its closure in 1991. Rio has repeatedly rejected allegations that emissions from the smelter were responsible for medical problems among local residents and former employees, or that the emissions damaged the surrounding environment. No date has yet been set for a court hearing in the case (Metal Bulletin, 2000e).

Vietnam.—Tiberon Minerals Ltd. (Canada) announced that it had begun exploration work at a diverse metals deposit in the northern part of Vietnam. Along with tin, other discoveries at the Nui Phao site, about 80 km north of Hanoi, include bismuth, gold, and tungsten (CRU Tin Monitor, 2001).

Current Research and Technology

Crown, Cork and Seal Corp. (Philadelphia, PA), the world's largest packaging manufacturer, announced the development of a new beverage can end that offers reduced metal usage and easier opening. Crown believes the new style can end will afford substantial savings in material costs and can be applied equally to tinplate or aluminum ends. Currently, almost all beverage can ends in the United States are aluminum, but tinplate shares the remaining worldwide market (Canning and Filling, 2000).

Researchers at Leeds University in the United Kingdom announced the development of a new method of recycling steel, including steel tinplate, that reportedly is cheaper, requires no presorting of scrap, and may even produce a stronger material. All steel producers recycle a significant proportion of steel scrap. Tin from tinplate scrap and copper from domestic incinerator scrap accumulates in the steel, posing a major quality problem for the steel industry unless properly controlled. Such impurities in anything other than small amounts can have harmful effects on ductility, causing defects in the worked material. Unless removed or controlled by careful scrap selection, these impurities could rise to unacceptable levels over the next few years due to increased recycling targets. The Leeds team discovered that the controlled addition of aluminum to the molten steel during recycling forms alloys with the tin and/or copper rendering both harmless. The new steel alloy may even be improved by this patented process. Initial studies show that the presence of aluminum causes an increase in the hardness of the steel, implying an increase in mechanical strength. The source of aluminum can be pure metal, an alloy, or a compound capable of dissociation at the operating temperature. To the researchers, an obvious source would be aluminum cans, currently recycled separately from steel cans; they reason that the recycling industry ultimately could change and not separate steel and aluminum used cans, but instead charge mixed loads of scrap, thereby saving on sorting costs. The addition of a metal as an alloying agent is a radical departure from conventional treatments such as those used in detinning plants or plants to extract unwanted metals by chemical or electrochemical methods (Tin International, 2000f).

During Metal Bulletin's 6th International Tin Conference held in San Diego, CA, May 7-9, a researcher speaking for the International Tin Research Institute (ITRI) (Uxbridge, UK) focused on the potential market for tin usage in flame retardants. The speaker noted that among the current types of flame retardants, tin's best opportunity for market penetration are in fields currently served by antimony trioxide. In the late 1980s ITRI developed a zinc stannate compound as a fire

Digitized by Google

retardant. This compound shows excellent smoke suppressant characteristics compared with antimony trioxide, but it is much more costly. ITRI continues its work in this area. The speaker indicated that the potential world replacement market for antimony trioxide is 36,000 t, of which 5,000 t may be a realistic target for tin over the next 10 years.

Outlook

Domestic demand for primary tin is expected to grow slowly in the next few years, at a rate of perhaps 1% per year. That rate could double in a few years, however, if new applications—especially those in which tin is substituted for toxic materials—find acceptance in the marketplace.

World tin reserves appear to be adequate to meet foreseeable demand. Secondary sources of tin are likely to remain an important component of tin supply, especially in the United States. The NDS sales are expected to continue in coming years and remain an important segment of domestic supply until the inventory is exhausted. Domestic tin needs, however, will probably continue to be met primarily through imports.

TITANIUM

By Joseph Gambogi

Domestic survey data and tables were prepared by Robin C. Kaiser, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

In 2000, the titanium industry was engaged in a high level of mineral exploration and development activity. In addition to exploration activity, a number of expansion projects were underway in the mineral and titanium dioxide (TiO_2) pigment industries. In the titanium metal industry, rising demand in certain sectors allowed producers to use some of the excess capacity.

Approximately 95% of titanium is consumed as TiO_2 pigment, a pigment used in paints, paper, and plastics. The superiority of TiO_2 as a pigment is attributed to its high opacity and brightness. Titanium metal alloys are used in aerospace and other industries for their high strength-to-weight ratio and corrosion resistance.

Titanium is not naturally found in its metallic form but occurs in many mineral forms, such as oxides, titanates, and silicotitanates. As the ninth most abundant element in the Earth's crust, titanium is present in most rocks and soil. The titanium-bearing minerals that have significant economic importance include ilmenite, leucoxene, and rutile.

Legislation and Government Programs

The Defense National Stockpile Center met its target for the sale of titanium sponge from the U.S. Government stockpile. For fiscal year 2000, 4,540 metric tons (t) of titanium sponge was offered for sale. In accordance with section 3305 of the National Defense Authorization Act for Fiscal Year 1996 (Public Law 104-106), 250 t of titanium sponge was transferred to the Army's Tank and Automotive Command for use in the weight-reduction portion of the main battle tank upgrade program. Fiscal year 2000 is the fifth year of this program, which provides for transfers of up to 250 metric tons per year (t/yr) of titanium sponge to continue through fiscal year 2003. Although this material is provided to the Army without charge, the law specifies that the Army will pay the costs for transportation and handling (U.S. Department of Defense, 2000). At yearend 2000, the National Defense Stockpile held 26,300 t of titanium sponge.

Production

Mineral Concentrates.—Commercial forms of titanium mineral concentrates include ilmenite, leucoxene, rutile, slag, and synthetic rutile. Mining of titanium minerals is usually performed using surface methods. A dredge is often used for the recovery of titanium-mineral placer deposits. Gravity spirals are used for wet separation of heavy minerals (HM), while magnetic and high-tension separation circuits are used to separate the HM constituents. Ilmenite is often further beneficiated to produce synthetic rutile and titaniferous slag. Although numerous technologies are used to produce synthetic rutile, nearly all are based on either selective leaching or thermal reduction of iron and other impurities in ilmenite. Titaniferous slag, with a TiO_2 content of up to 95%, is produced using a pyrometallurgical process.

Australia, Canada, India, Norway, and South Africa led the world's production of titanium mineral concentrate. U.S. mineral concentrate producers included E.I. du Pont de Nemours & Co. Inc. (DuPont), Kerr-McGee Chemical Corp., and Iluka Resources Inc. (a subsidiary of Iluka Resources Ltd.). DuPont's Trail Ridge mining operations in Starke, FL, produced a mixed product containing ilmenite, leucoxene, and rutile that was used as a feedstock in DuPont's TiO_2 pigment operations. Iluka's mining operations in Green Cove Springs, FL, and Stony Creek, VA, produced both rutile and ilmenite concentrates. Kerr-McGee's operation in Mobile, AL, produced synthetic rutile from purchased ilmenite concentrate. Titanium slag was not produced in the United States.

Altair International Inc. was proceeding with feasibility

Titanium in the 20th Century

In the early 1900s, titanium minerals were primarily used in steelmaking for railways and as an arc stabilizer in electric lamps. Although little statistical data are available, domestic consumption of titanium minerals prior to 1920 was less than 2,000 metric tons per year, and domestic production was less than a few hundred tons per year. Composite pigments, containing approximately 25% titanium dioxide (TiO_2) and 75% barium sulfate, were not introduced to the commercial market until 1919. Commercial production of relatively pure TiO_2 pigments did not start until the early 1940s, and commercial production of titanium metal followed shortly thereafter.

In 2000, domestic consumption of titanium minerals was about 1.42 million tons (TiO_2 content). Imports were about 1.06 million tons (TiO_2 content), and roughly 0.3 million tons (TiO_2 content) of titanium minerals were produced. About 95% of titanium mineral concentrates produced was used in TiO_2 pigments, while the remainder was used in welding rod coatings and to manufacture metals, carbides, and chemicals. TiO_2 pigments produced in the United States, valued at about $2.6 billion, were used mainly in coatings (49.5%), plastics (21.3%), and paper (20.4%). Other uses of TiO_2 pigments (8.8%) in 2000 included catalysts, ceramics, coated textiles, floor coverings, printing ink, and roofing granules. The value of sponge metal consumed in the United States was about $170 million. Since its commercialization, the major end use for titanium metal has been in aerospace products. Other end uses include armor, chemical processing equipment, consumer goods, power generation equipment, marine goods, medical implants, and sporting goods.

Digitized by Google

studies at its heavy mineral deposits near Camden, TN. In 2000, Altair began construction of a pilot mineral separation plant. If further studies are successful, Altair expects to produce 250,000 t to 300,000 t of a high TiO_2 mineral concentrate (North American Minerals News, 2000).

Iluka Resources studied the feasability of increasing capacity by 70% in four years at its Florida and Virginia mineral operations. The expansion project was expected to begin in 2001 (Iluka Resources Ltd., March 9, 2001, Annual report, accessed August 28, 2001, at URL http://www.iluka.com/files/annual%20report%202000.pdf).

Metal.—Titanium sponge is the rudimentary form of titanium metal. The initial production step involves the chlorination of titanium-containing mineral feedstocks to produce titanium tetrachloride ($TiCl_4$). The next step is usually based on the Kroll process where $TiCl_4$ is reduced with magnesium to form titanium sponge. In 2000, titanium sponge was produced in China, Japan, Kazakhstan, Russia, Ukraine, and the United States. U.S. producers of titanium sponge included The Alta Group, Allegheny Technologies Inc., and Titanium Metals Corp. At yearend, domestic operating capacity of titanium sponge was estimated to be 21,600 t/yr (table 2). Data on domestic production of titanium sponge have not been published in order to avoid disclosing company proprietary data.

U.S. production of ingot decreased by about 3% compared with that of 1999 (table 3). Titanium ingot is produced by melting titanium sponge or scrap or a combination of both usually with various other alloying elements, such as aluminum and vanadium. Electron beam, plasma, and vacuum arc reduction are the commercial melting methods used to produce ingot. In 2000, commercial ingot production capacity existed in France, Germany, Japan, Russia, the United Kingdom, and the United States.

Titanium mill products are produced from the drawing, forging, and rolling of titanium ingot or slab into products of various sizes and shapes. These mill products include billet, pipe and tube, plate, rod and bar, sheet and strip, wire, etc. Major producers of titanium mill products were located primarily in China, Europe, Japan, Russia, and the United States. More than 30 domestic companies were known to produce titanium mill products and castings from ingot and billet. In 2000, U.S. production of mill products increased by 7% compared with that of 1999.

Titanium castings are commonly produced by two techniques: investment casting and rammed graphite mold casting. In 2000, U.S. producers of titanium castings included Cast Alloys Inc., Coastcast Corp., Flowserve Corp., Howmet Corp., Precision Cast Parts Corp., Reactive Alloy Manufacturing Inc., RTI International Metals Inc., Selmet Inc., and Titanium Industries Inc.

Ferrotitanium is usually produced by induction melting of titanium scrap with iron or steel. U.S. producers of ferrotitanium included Galt Alloys Inc., Global Titanium Inc., and Shieldalloy Metallurgical Corp. The two standard grades of ferrotitanium contain 40% and 70% titanium. Data on production of ferrotitanium were not available.

Honeywell International Inc. announced it was investing $8.5 million in The Alta Group of its wafer fabrication materials division to meet the surge in demand for high purity titanium.Alta is the largest producer of high purity titanium ranging from 99.995% titanium to 99.9995% titanium. According to the company, demand had increased because of new semiconductor fabrication capacity coming online (Honeywell International Inc., November 1, 2000, Honeywell Electronic Materials (HEM) ALTA announces $8.5 million investment to meet demand for high purity titanium, accessed August 24, 2001, at URL http://www.electronicmaterials.com/mediakit/news/fb110100.htm).

TiO_2 Pigment.—TiO_2 pigment is produced from titanium mineral concentrates by either the chloride process or the sulfate process. In the sulfate process, ilmenite or titanium slag is reacted with sulfuric acid. Titanium hydroxide is precipitated by hydrolysis, filtered, and calcined. In the chloride process, rutile is converted to $TiCl_4$ by chlorination in the presence of petroleum coke. $TiCl_4$ is oxidized with air or oxygen at about 1,000° C, and the resulting fine-size TiO_2 is calcined to remove residual chlorine and any hydrochloric acid that may have formed in the reaction. Aluminum chloride is added to the $TiCl_4$ to assure that virtually all the titanium is oxidized in the rutile crystalline form.

Although either process may be used to produce pigment, the decision to use one process instead of the other is based on a number of factors, including raw material availability, freight, and waste disposal costs. In finishing operations, the crude form of the pigment is milled to produce a controlled distribution of particle size and surface treated or coated to improve its functional behavior in different media. Some typical surface treatments include alumina, silica, and organic compounds.

TiO_2 pigment produced by either process is categorized by crystal form as either anatase or rutile. Rutile-type pigment is less reactive with the binders in paint when exposed to sunlight than is the anatase type and is preferred for use in outdoor paints. Anatase pigment has a bluer tone than the rutile type, is somewhat softer, and is used mainly in indoor paints and in paper manufacturing. Depending on the manner in which TiO_2 pigment is produced and subsequently finished, TiO_2 pigment can exhibit a range of functional properties, including opacity, durability, dispersion, and tinting.

World production of TiO_2 pigment was estimated to have increased slightly compared with that of 1999. In 2000, France, Germany, Japan, the United Kingdom, and the United States were the leading producing countries of TiO_2 pigment, while DuPont and Millennium Inorganic Chemicals Inc. were the largest corporate producers of TiO_2 pigment. U.S. production of TiO_2 pigment in 2000 was 1.40 million metric tons (Mt), a 3.6% increase compared with that of 1999. U.S. producers of TiO_2 pigment were DuPont, Millennium, Kerr-McGee, and Louisiana Pigment Co. LP (a NL Industries Inc. and Huntsman Corp. joint venture). In addition, TOR Minerals International Inc. produced a buff pigment from finely ground synthetic rutile (table 4). Capacity utilization for the domestic pigment industry was about 89%.

DuPont completed an expansion at its New Johnsonville, TN, TiO_2 pigment facility by adding a third line to the existing chloride route plant. New Johnsonville is the world's largest TiO_2 pigment facility (Industrial Minerals, 2000k). At yearend, capacity at New Johnsonville was estimated to be 380,000 t/yr.

Hitox Corp. of America changed its name to TOR Minerals International. TOR Minerals operates a facility in Corpus Christi, TX, where buff TiO_2 pigment is produced by fine grinding of synthetic rutile (Industrial Minerals, 2000b).

In April, Kerr-McGee completed the acquisition of Kemira Oyj's TiO_2 pigment facility at Savannah, GA. The Savannah

Digitized by Google

facility included both a chloride-route plant and a sulfate-route plant. Kerr-McGee planned to upgrade these facilities in 2001 (Kerr-McGee Chemical Corp., April 6, 2000, Kerr-McGee completes acquisition of Kemira's Savannah plant, accessed August 21, 2001, at URL http://www.kerr-mcgee.com/news2000/040600.html).

Consumption

Mineral Concentrates.—Titanium mineral concentrates are primarily used as a feedstock for TiO_2 pigment production. About 5% of global mineral consumption is for miscellaneous uses such as ceramics, glass, steel, titanium metal, and welding rod coatings.

Based on TiO_2 content, domestic consumption of titanium minerals concentrates was 1.42 Mt, a 3% increase compared with that of 1999. Although consumption of ilmenite and slag decreased by 5%, consumption of rutile and synthetic rutile increased by 20% compared with that of 1999. On a gross weight basis, about 98% of the domestic consumption of titanium mineral concentrates was used to produce TiO_2 pigment.

Consumption data for titanium concentrates are developed by the U.S. Geological Survey from a voluntary survey of domestic operations. Of the 19 operations canvassed, 14 responded, representing 68% of the data in table 6. Data for nonrespondents were estimated based on prior-year consumption with some adjustments for present-year trends (table 6).

Metal.—Overall consumption of titanium sponge and scrap decreased by 8% compared with that of 1999. Scrap consumption by the titanium industry decreased by 15% compared with that of 1999, while sponge consumption was nearly unchanged. Scrap supplied a calculated 50% of ingot feedstock. Estimated U.S. mill product usage by application was as follows: aerospace, 60%, and nonaerospace uses, 40%. Nonaerospace uses included those in the consumer goods, marine, medical, oil and gas, pulp and paper, and specialty chemical industries. Reported consumption of titanium products in steel and other alloys increased by 3% compared with that of 1999 (tables 3, 7).

TiO_2 Pigment.—Global consumption of TiO_2 pigment was estimated to have increased moderately compared with that of 1999. In the United States, apparent consumption of TiO_2 pigment was about 1.15 Mt, virtually unchanged from 1999. The largest uses of TiO_2 pigment, based on TiO_2 pigment shipments in the United States, were paint and coatings (49.5%), paper (20.4%), and plastics (21.3%). Other uses of TiO_2 included catalysts, ceramics, coated fabrics and textiles, floor coverings, printing ink, and roofing granules.

In the paint and coatings industry, TiO_2 pigment is used in architectural, equipment, and special-purpose applications and is widely used in white and color formulations. The TiO_2 content for paint and coatings varies significantly.

The plastics industry primarily consumes rutile-grade pigment. TiO_2 pigment is used in a variety of plastics applications. Primarily, TiO_2 pigment provides opacity and acts as a barrier against ultraviolet light degradation. TiO_2 pigment often is introduced as pelletized concentrate containing up to 50% by weight TiO_2 in a carrier resin; however, liquid and dry concentrates also are used by the industry. The TiO_2 content for plastics normally ranges from 3% to 25% by weight of the finished product.

TiO_2 pigment in paper products provides opacity and brightness. The paper industry consumes TiO_2 pigment as filler and in coatings. Paper products contain a high percentage of non-TiO_2 base minerals as filler material with the typical TiO_2 content less than 5% of the dry weight of paper. Anatase-grade pigment is preferred in the paper industry because it is less abrasive to papermaking machinery (tables 5, 8).

Stocks

On a TiO_2 content basis, yearend consumer inventories of titanium mineral concentrates decreased by 17% compared with those of 1999 (table 9). While consumer stocks of rutile and synthetic rutile rose by 5%, stocks of ilmenite and slag decreased by 24% compared with that of 1999.

On a gross weight basis, yearend producer stocks of TiO_2 pigment were about 141,000 t, a 3% increase compared with those of 1999. During the year, pigment stocks had fallen to a low of 124,000 t in September, then rose significantly in the last quarter.

Compared with those of 1999, industry stocks of titanium sponge and scrap decreased by 37% and 56%, respectively. Reduced consumption of ingot in 2000 resulted in a 33% increase in ingot stocks compared with those of 1999.

Prices

The yearend published price range for bulk rutile mineral concentrates was $470 to $500 per ton, a decrease of 6% compared with that of 1999. Meanwhile, the price range for bagged rutile concentrates commonly used in the welding rod coatings industry was $480 to $570 per ton, an increase of 2% compared with that of 1999. Owing in part to changes in currency exchange rates, yearend prices of ilmenite concentrates decreased by 3% compared with those of 1999. Published prices for titanium slag were not available. Based on U.S. Customs value of imports, however, prices for Canadian slag increased by 9%, while prices for South African slag were unchanged compared with those of 1999 (table 10).

Yearend published prices for anatase- and rutile-grade pigment were unchanged. Based on U.S. Customs value of imports, the average unit value of unfinished pigments and TiO_2 pigments with less than 80% TiO_2 content decreased by 8% and 6%, respectively. The average unit value of imported TiO_2 pigment with more than 80% TiO_2 content was unchanged.

The averaged yearend prices for ferrotitanium decreased by 66% compared with that of 1999. Average yearend prices unprocessed scrap turnings increased by 45% compared with those of 1999.

Foreign Trade

Mineral Concentrates.— The U.S. Census Bureau collects import and export data for mineral concentrates on a gross weight basis. Imports and exports of titaniferous iron ore from Canada (classified as ilmenite by the U.S. Census Bureau) are excluded from ilmenite statistics in this report. In 2000, the leading import sources of ilmenite were Australia (54%), Ukraine (31%), and India (8%). Imports of ilmenite for 2000 were 386,000 t, a slight decrease compared with those of 1999. Although imports of ilmenite from Australia decreased by 17%,

Digitized by Google

imports from Ukraine increased by 14%. Owing to a significant drop in imports from Canada and South Africa, gross imports of titanium slag for 2000 fell to 533,000 t, a 21% decrease compared with those of 1999. Increases in natural rutile imported from Australia and South Africa helped to increase overall imports of natural rutile by 18%. Synthetic rutile imports, primarily from Australia, were 173,000 t, a 46% increase compared with imports in 1999 (table 12). Although small relative to imports, exports of titanium mineral concentrates were 18,900 t, a 102% increase compared with exports in 1999 (table 11).

Metal.—Imports of titanium metal are primarily in the form of titanium sponge (37%) and waste and scrap (39%). Compared with those of 1999, imports of unwrought metal, including sponge and waste and scrap, increased by 14% in 2000. Imports of wrought products and castings were unchanged. Although the United States was import reliant on unwrought titanium, the Nation was a net exporter of wrought products. In 2000, exports of wrought products were 35% of all metal exports. Total metal exports for 2000 decreased by 7% compared with those of 2000 (table 13).

TiO_2 Pigment.—Although the United States was a net exporter of TiO_2 pigment, a significant quantity of TiO_2 pigment was imported. During 1999, TiO_2 pigment imports increased by 13%, and the leading import sources of titanium pigment were Canada, France, Germany, Japan, and Spain. Compared with those of 1998, imports of titanium pigment containing more than 80% TiO_2 increased by 25% to 190,000 t; other titanium pigment increased by 58% to 9,320 t; and titanium oxide remained nearly unchanged at 25,700 t (table 14). Exports of TiO_2 pigment were 344,000 t, nearly unchanged compared with those of 1998. Exports of titanium oxide (unfinished pigment) were 39,000 t, a 7% decrease compared with those of 1998.

As has been the case for many years, the United States was a net exporter of TiO_2 pigments and oxides. In 2000, exports outpaced imports by more than 2 to 1. Compared with those of 1999, exports of TiO_2 pigment and oxides in 2000 increased by 21% on a gross weight basis. Meanwhile, imports of TiO_2 pigment and oxides decreased by 3%.

World Review

In 2000, Australia, Canada, India, Norway, and South Africa continued to lead the world's production of titanium mineral concentrates (table 15). Production of titanium mineral concentrates was estimated to be slightly higher compared with that of 1999.

Australia.—The Murray Basin in southeastern Australia has become an area of considerable interest to the titanium mineral industry. The basin covers a large area in New South Wales, Victoria, and South Australia, and numerous deposits are in various stages of exploration and development. According to one industry review, the indicated and inferred resources of contained heavy minerals in the Murray Basin are about 44 Mt (TZ Minerals International Pty. Ltd, 2000).

Basin Minerals Ltd., formerly Craton Resources NL, increased its estimate of inferred resources at its Douglas project in the Murray Basin. Inferred resources were estimated to be 20.8 Mt of concentrate. The Douglas project includes the Acapulco, Bondi East, Bondi, and Echo deposits. During 2000, Basin Minerals was conducting a prefeasibility study (Industrial Minerals, 2000a).

BeMax Resources NL reported the completion of a prefeasibility study on its Ginkgo heavy minerals project with Probo Mining Pty. Ltd. in the Murray Basin. According to BeMax, the study found no major impediments that would prevent the Ginkgo project from proceeding through a feasibility study. The indicated resource at Ginkgo was reported to be 252 Mt containing 2.8% heavy minerals (Industrial Minerals, 2001).

Murray Basin Minerals NL doubled the estimate of the heavy mineral resource at its Mercunda deposit in the Murray Basin. At yearend 2000, the resource was estimated to be 44 Mt of ore containing 3.4% heavy minerals. Feasibility studies were underway in 2000.

Murray Basin Titanium Pty. Ltd., a joint venture of RZM Pty. Ltd. and Sons of Gwalia Ltd., began construction of a mine site at its Wemen deposit in the Murray Basin. Mine plans included a separation plant at nearby Mildura. Production at the 30,000-t/yr plant was expected to begin in 2001. Other deposits under study included Cylinder, Birthday Gift, Karra, Jacks Tank North, Jacks Tank South, and Finnigans Tank (Industrial Minerals, 2000i).

Tiwest Pty. Ltd. announced plans to increase capacity at its TiO_2 pigment operation near Kwinana, Western Australia. Capacity is expected to increase to 95,000 t/yr (a 10% increase) in 2001. Tiwest is a 50-50 joint venture between KMCC Western Australia Pty Ltd., a subsidiary of Kerr-McGee Chemical LLC, and Ticor Resources Pty. Ltd. (Industrial Minerals, 2000g).

Brazil.—Millennium Inorganic Chemicals Inc. made plans to lower operating costs and improve ore recovery at the Titananio do Brazil S.A. operation near Mataraca, Paraiba. The project was expected to be completed by yearend 2001 and could raise ilmenite capacity at Mataraca to 120,000 t/yr, an increase of about 30,000 t/yr (Millennium Inorganic Chemicals Inc., 2000).

Canada.—Rio Tinto plc was in the process of increasing capacity at its upgraded slag (UGS) plant at Sorel, Quebec, to 250,000 t/yr (a 50,000 t/yr increase). Future expansions of its UGS plant are expected to increase capacity to 350,000 t/yr. Compared with the standard grade of slag from Sorel, UGS has a higher TiO_2 content and is suitable for use by chloride-route pigment producers (Rio Tinto plc, 2000).

Syncrude Canada Ltd. continued to investigate the recovery of heavy minerals from tailings of the Athabasca oil sands operations in northern Alberta. According to Syncrude, 220,000 t/yr of TiO_2 could be recovered. In 2000, Syncrude's research was focused on finding an alternative to calcining as a method for bitumen removal (J. Oxenford, Syncrude Canada Ltd., written commun. February 1, 2001).

NAR Resources Ltd. continued to study its heavy minerals deposit near Truro, Nova Scotia. At yearend 2000, the company was conducting a drilling program to confirm positive results of seismic studies and previous shallow drilling (NAR Resources Ltd., January 30, 2001, Quarterly report, accessed August 21, 2001, at URL http://www.nar-resources.com/Financial/quarter1.2001.pdf).

Germany.—Sachtleben Chemie GmbH neared completion of a 25% capacity expansion at its Duisberg sulfate-route TiO_2 pigment facility. The company planned to increase capacity to 100,000 t/yr through process improvements (Sachtleben Chemie GmbH, July 9, 2000, Capacity to increase to 100,000 tonnes titanium dioxide p.a., accessed August 21, 2001, at URL

Digitized by Google

http://www.sachtleben.de/h/e/new/0970e.phtml?id=11,2).

India.—Kerala Minerals and Metals Ltd. made plans for a 2-year project to increase titanium mineral and pigment capacities at its Charava complex. A new separation plant is expected to increase ilmenite production capacity to 300,000 t/yr. By 2002, synthetic rutile capacity will be increased to 130,000 t/yr from 30,000 t/yr, and TiO_2 pigment capacity is expected to be increased to 60,000 t/yr from the current [2000] 22,000 t/yr (Industrial Minerals, 2000j).

Iscor and Mineral Deposits Ltd. formed an agreement to study several heavy mineral sands deposits in Tamil Nadu. The Kudiraimozhi deposit is located about 90 kilometers southwest of Tuticorin, with an estimated resource of 23 Mt of ilmenite and 1.3 Mt of rutile. Two other deposits under study include one near Sattankulam and another stretching between the cities of Navaladi and Sattankulam (Industrial Minerals, 2000h).

Kazakhstan.—Ust-Kamengorsk Titanium and Magnesium Combine (UKTMC) commissioned a slag plant at its titanium metal facility in Ust-Kamengorsk (Analysis and Strategic Research Center, October 2000, N. Nazarbayev visited eastern Kazakhstan oblast, accessed October 24, 2001, via URL http://www.president.kz/articles/News/News.asp?lng=&art=news2001_october). UKTMC planned to commission its Satpayev ilmenite mine near Bekmir in 2001 (Interfax International Ltd., 2000).

Kenya.—Tiomin Resources Inc. submitted an environmental impact assessment (EIA) for its Kwale mineral sands project to the Ministry of Environment and Natural Resources. Approval of the EIA was pending at yearend (Tiomin Resources Inc., March 31, 2001, Poised for development—2000 annual report, accessed August 21, 2001, at URL http://www.tiomin.com/i/pdf/tio-ar00.pdf).

Malaysia.—Huntsman Tioxide was in the process of increasing capacity at its Teluk Kalung sulfate-route TiO_2 pigment facility. When completed, capacity will be expanded to 56,000 t/yr (a 6,000 t/yr increase) through process improvements (Hunstman Corp, March 31, 2000, Huntsman Tioxide announces capacity increases, accessed October 24, 2001, at URL http://www.huntsman.com/tioxide/ShowPage.cfm?PageID=925&News_ID=647).

TOR Minerals acquired Malaysian Titanium Corp. (MTC). MTC's Ipoh facility is the sole supplier of synthetic rutile for TOR Minerals' buff TiO_2 pigment facility in Corpus Christi, TX (Industrial Minerals, 2000c).

Mozambique.—Kenmare Resources plc acquired the wet separation plant from BHP Minerals' defunct Beenup mining operation in Australia. The plant was shipped to Kenmare's Moma Mineral Sands project in Mozambique. Kenmare expects to begin production by yearend 2002. Capacity at Moma is projected to reach 600,000 t/yr of ilmenite and 16,500 t/yr of rutile (Industrial Minerals, 2000e).

WMC Ltd., Southern Mining Corp., and the state-owned Industrial Development Corp. were proceeding with the development of the Corridor Sands project in Mozambique. In 2000, a feasibility study concluded there were no technical issues to be resolved and the project could proceed. Reserves were estimated to be 45 Mt of ilmenite (Industrial Minerals, 2001).

Netherlands.—In May, Kerr-McGee completed the acquisition of Kemira's TiO_2 pigment plant at Botlek. Capacity at Botlek is based on chloride route technology and is reported to be 56,000 t/yr (Kerr-McGee Chemical Corp., May 4, 2000, Kerr-McGee completes acquisition of Botlek pigment plant, accessed August 21, 2001, at URL http://www.kerr-mcgee.com/news2000/050400.html).

Saudi Arabia.—Kerr-McGee sold its 25% interest in National Titanium Dioxide Co. Ltd., also known as the Cristal joint-venture, to the remaining joint venture partners Shairco for Trading and Contracting, the National Industrialization Co., and Gulf Investment Corp. Cristal is the only TiO_2 pigment producer in Saudi Arabia with 70,000 t/yr of chloride-route capacity (Industrial Minerals, 2000f).

South Africa.—Iscor Ltd. was proceeding with plans to develop its Hillendale deposit near Richards Bay. The company planned to begin mining operations in 2001. In the second phase of the project, Iscor hopes to construct a 250,000-t/yr slag plant at nearby Empangeni. Hillendale reserves are estimated to contain about 4 Mt of heavy minerals (Industrial Minerals, 2000d).

Spain.—Huntsman Corp. was in the process of increasing capacity at its Huelva sulfate-route TiO_2 pigment facility. When completed, capacity will be expanded to 90,000 t/yr (a 17,000 t/yr increase) through process improvements (Huntsman Tioxide, March 9, 2001, Huntsman Tioxide approves $40M expansion of Huelva, Spain plant, accessed August 21, 2001, at URL http://www.huntsman.com/tioxide/ShowPage.cfm?PageID=925&News_ID=642).

United Kingdom.—In September, Huntsman Corp. announced plans to proceed with the construction of a new chloride-route TiO_2 pigment plant at its Greatham facility. The new plant is expected to be completed in 2002 and is expected to bring capacity up to 100,0000 t/yr (Huntsman Tioxide, September 22, 2000, Huntsman Tioxide announces go-ahead for new £50 million plant at Greatham, Deeside, UK, accessed August 21, 2001, at URL http://www.huntsman.com/tioxide/ShowPage.cfm?PageID=925&News_ID=644).

Outlook

Demand for TiO_2 pigment is expected to remain near its current level in the coming year. Over the next 5 years, global economic growth is expected to increase TiO_2 pigment consumption by 3% to 4% per year. Because approximately 95% of all titanium minerals are consumed to produce TiO_2 pigment, consumption of titanium minerals is expected to follow a similar trend.

In the titanium metal industry, the resumption of some aerospace orders is expected to increase demand for some titanium metal products over the coming year. An overall economic slowdown, however, may result in negative growth within the industry. Long-term growth in passenger traffic and nonaerospace markets is expected to result in a 5% per year demand growth over the next decade.

e/ Estimated. r/ Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total." -- Zero.

1/ Totals and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through July 13, 2001.

3/ Ilmenite is also produced in Canada and South Africa, but this output is not included here because most of it is duplicative of output reported under "Titaniferous slag," and the rest is used for purposes other than production of titanium commodities, principally steel furnace flux and heavy aggregate.

4/ Reported figure.

5/ Excludes production of unbeneficiated anatase ore.

6/ Includes rutile to avoid revealing company proprietary data. Rounded to one significant digit.

7/ Included with ilmenite to avoid revealing company proprietary data; not included in "Total."

8/ Slag is also produced in Norway, but this output is not included under "Titaniferous slag" to avoid duplicative reporting.

TUNGSTEN

By Kim B. Shedd

Domestic survey data and tables were prepared by Jason T. Collins, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Tungsten is a whitish-gray metal with many unique properties and a wide variety of uses (see Tungsten in the 20th Century section of this report). During 2000, U.S. demand for tungsten increased. Worldwide, the availability of tungsten raw materials from China was limited by export quotas, exports of stockpiled Russian tungsten materials decreased, and prices increased. The important U.S. and world tungsten statistics for 2000 and the previous 4 years are listed in table 1.

Most data in this report have been rounded to three significant digits. Totals and percentages were calculated from unrounded numbers. Unless otherwise specified, all statistics in this report are in metric tons of contained tungsten.

Tungsten prices and many tungsten statistics from other sources are quoted in units of tungsten trioxide (WO_3). The short ton unit, which is used in the United States, is 1% of a short ton (20 pounds), and WO_3 is 79.3% tungsten. A short ton unit of WO_3, therefore, equals 20 pounds of WO_3 and contains 7.19 kilograms (kg) (15.86 pounds) of tungsten. The metric ton unit, which is used in most other countries, is 1% of a metric ton (10 kg). A metric ton unit of WO_3, therefore, equals 10 kg of WO_3 and contains 7.93 kg (17.48 pounds) of tungsten.

Legislation and Government Programs

As a result of reviews conducted by the International Trade Administration, U.S. Department of Commerce, and the U.S. International Trade Commission during 1999, the 151% duty on imports of tungsten ore concentrates from China was revoked effective January 1, 2000 (International Trade Administration, 1999; U.S. International Trade Commission, 1999).

The Defense National Stockpile Center (DNSC), U.S. Department of Defense, continued its negotiated sales of tungsten materials from the National Defense Stockpile (NDS). Ten bid offerings were held during calendar year 2000—three for tungsten ores and concentrates and seven for ferrotungsten, tungsten carbide powder, and/or tungsten metal powder. As shown in table 2, 2,610 metric tons (t) of tungsten contained in ores and concentrates, ferrotungsten, tungsten metal powder, and tungsten carbide powder was sold during the calendar year. During fiscal year 2000 (October 1, 1999, through September 30, 2000), 2,320 t of contained tungsten was sold; this represented 94% of the maximum amount available for sale in the Annual Materials Plan (AMP). Of the tungsten materials sold prior to September 30, 2000, the following quantities, in metric tons of contained tungsten, had not been shipped by the end of the 2000 fiscal year: tungsten ores and concentrates, 1,560; tungsten carbide powder, 309; and ferrotungsten, 123 (U.S. Department of Defense, 2001, p. 48). The quantities of tungsten materials remaining in the stockpile at the end of the calendar year, including those committed for sale and pending shipment, are listed in tables 1 and 2.

The AMP for fiscal year 2001 (October 1, 2000, through September 30, 2001) maintained the maximum quantities of tungsten materials that could be sold, in metric tons of contained tungsten, at the following levels: tungsten ores and concentrates, 1,810; tungsten carbide powder, 454;

Tungsten in the 20th Century

In 1900, the main use of tungsten was to make ferrotungsten, which was used to produce steel. Lesser amounts of tungsten were used to make aluminum-tungsten alloys and tungsten-copper alloys, which were used to make propeller blades. Sodium tungstate was used to make fabric colorfast or flame resistant, and because of its ability to fluoresce, calcium tungstate was used to make screens for X-ray apparatus. Tungsten chemicals were also used as pigments for coloring glass. Although some tungsten was mined in the United States in 1900, most of the U.S. supply was imported. The leading producers of tungsten ores were Australia; Austria-Hungary, at the time a dual monarchy in Central Europe; England; Germany; and Saxony, an independent kingdom at the time that is now part of Germany. Few statistics on tungsten production and use are available for 1900. World production of tungsten concentrates was probably less than 1,500 metric tons contained tungsten. U.S. production was estimated to be approximately 20 tons contained tungsten.

In 2000, tungsten was used in many diverse commercial, industrial, and military applications. The largest use was as tungsten carbide in cemented carbides, which were wear-resistant materials used by the metalworking, mining, and construction industries. Tungsten metal wires, electrodes, and contacts were used in lighting, electronic, electrical, heating, and welding applications. Tungsten was also used to make heavy metal alloys for armaments, heat sinks, radiation shielding, and weights and counterweights; superalloys for turbine blades; tool steels; and wear-resistant alloy parts and coatings. Tungsten composites were used as a substitute for lead in bullets and shot. Tungsten chemicals were used in catalysts, inorganic pigments, high-temperature lubricants, and semiconductors. The U.S. apparent consumption of all tungsten materials was 14,300 tons in 2000. No tungsten was mined in the United States. U.S. tungsten supply comprised imports, tungsten-bearing scrap, releases from industry stocks, and sales of excess tungsten materials from the National Defense Stockpile. World production of tungsten concentrates was approximately 37,400 tons contained tungsten. More than three-fourths of this production was from China. Austria, Bolivia, Portugal, and Russia were also significant producers of tungsten concentrates.

Digitized by Google

ferrotungsten, 136; and tungsten metal powder, 68 (Defense National Stockpile Center, 2000a). In October, the DNSC proposed a change in its sales program for tungsten ores and concentrates. DNSC planned to sell ores and concentrates under long-term contracts. The entire AMP quantity would be offered at one time, with an option to purchase additional quantities during the next four fiscal years (Defense National Stockpile Center, 2000b).

In 2000 and early 2001, the U.S. Fish and Wildlife Service (FWS) granted final approval to two tungsten-based shot products for hunting waterfowl and coots—tungsten-matrix shot (95.9 parts tungsten to 4.1 parts polymer) and tungsten-nickel-iron shot (50% tungsten, 35% nickel, and 15% iron, by weight) (U.S. Fish and Wildlife Service, 2000, 2001). These approvals bring the number of tungtsen-based shot products approved for hunting waterfowl and coots to four. In 1999, FWS gave approval to tungsten-iron shot and tungsten-polymer shot.

The "Green Ammunition" program was part of a joint service effort chaired by the U.S. Army Armaments Research, Development and Engineering Center to eliminate the use of hazardous materials in the production of small caliber ammunition. One component of the program was to find an alternative for the lead-antimony cores in small-caliber ammunition projectiles. During the year, two candidate materials, tungsten-nylon and tungsten-tin composites, were tested to evaluate the following: their leaching characteristics in sand, soil, and water; the biological uptake of the materials by earthworms; and the recovery and recycling of tungsten and other metals following the use of bullets made from these materials (Middleton, 2000, p. 13-21).

Production

Domestic production statistics for tungsten are based on data collected by the U.S. Geological Survey (USGS) by means of two separate voluntary surveys. Statistics that result from these surveys are listed in tables 1 and 3.

The annual Tungsten Ore and Concentrate Survey covered the production, purchases, disposition, and stocks of tungsten ores and concentrates. No tungsten was mined in the United States in 2000. In early 2001, Avocet Mining plc sold the land and residual assets associated with the Pine Creek Mine in Bishop, CA (Avocet Mining plc, 2001).

The monthly Tungsten Concentrate and Tungsten Products Survey canvassed companies that produced tungsten carbide powder, tungsten chemicals, and/or tungsten metal powder from ammonium paratungstate, tungsten-bearing scrap, and tungsten concentrate. The USGS received responses from 11 of the 12 processing operations on the survey; estimates were made for the nonresponding operation.

Major U.S. processors of tungsten materials operating in 2000 included Allegheny Technologies Inc.'s Metalworking Products business, Huntsville, AL; General Electric Co., Euclid, OH; Kennametal Inc., Latrobe, PA, and Fallon, NV; OM Group, Inc. (OMG), Midland, MI, and St. George, UT; and Osram Sylvania Inc., Towanda, PA.

In 2000, U.S. processors consumed slightly less tungsten concentrate, approximately the same amount of tungsten-bearing scrap, and 20% more ammonium paratungstate than they did in 1999. Domestic production of ammonium paratungstate was higher than that of 1999. Total net production of all primary tungsten products (hydrogen-reduced metal powder, tungsten carbide powder, and tungsten chemicals) increased by 10% in 2000 compared with that of 1999.

During the year, Avocet Tungsten Inc. permanently closed its Bishop, CA, tungsten processing plant. According to the company, while the plant was competitive in some value added products such as ammonium metatungstate and pressed powders, the basic tungsten conversion business could not compete with other processing operations. Avocet Tungsten's last production of ammonium paratungstate from stockpiled ore concentrates was in March. The plant and associated equipment were sold at auction in July (Avocet Mining plc, 2000b; Ryan's Notes, 2000). With the closure of the Bishop plant, the United States had two remaining plants that processed tungsten concentrates—Kennametal's tungsten carbide plant in Fallon, NV, and Osram Sylvania's tungsten processing plant in Towanda, PA.

OMG reportedly planned to increase production of ammonium paratungstate at its processing plant in St. George, UT, late in the year. Some of the increased production was to be from reprocessing tungsten carbide powder purchased from the DNSC. The plant typically used hard and soft cemented carbide scrap as feed for its ammonium paratungstate production (Magdics, 1998, p. 22; Platt's Metals Week, 2000).

N.V. Union Minière S.A. of Brussels, Belgium, resolved the technical problems associated with the startup of its Nanodyne Inc. nanocrystalline powder plant in Laurinburg, NC. The plant was designed to have the capacity to produce 500 metric tons per year (t/yr) of composite metal powders, such as tungsten carbide-cobalt powders, by using a spray-conversion process. The Nanodyne plant is adjacent to Union Minière's Carolmet Cobalt Products plant, which produced cobalt metal powder and salts (American Metal Market, 1998; N.V. Union Minière S.A., 2001, p. 13).

In November, Praxair, Inc. and Advance Research Chemicals, Inc. announced that they had formed a strategic alliance to develop, manufacture, and market high-purity tungsten hexafluoride for the semiconductor industry. Production was to occur at a new plant in Catoosa, OK. The plant's capacity was approximately 4.5 t/yr, gross weight, of tungsten hexafluoride (Praxair, Inc., 2000).

Consumption

U.S. apparent consumption of all tungsten materials, as calculated from net imports, primary and secondary production, and changes in Government and industry stock levels, was 14,300 t in 2000, an increase of 11% from that of 1999. In 2000, a decrease in net imports was more than equaled by shipments of tungsten materials from the NDS and an increase in scrap consumption.

Statistics on consumption of tungsten in end-use applications by U.S. metal consumers were developed from the voluntary Consolidated Consumers Survey. For this survey, nearly 70 tungsten consumers were canvassed on a monthly or annual basis. Reported consumption and stocks data in tables 1 and 4 include estimates to account for nonrespondents. Total U.S. reported consumption of tungsten materials to make end-use products increased by 5% in 2000 compared with that of 1999. The increase was the result of increased consumption by producers of mill products for lighting and other industries, superalloys, and other alloys. As compared with 1999, in 2000,

Digitized by Google

U.S. industry consumed more tungsten metal powder and tungsten scrap, less ferrotungsten and tungsten chemicals, and approximately the same amount of tungsten carbide powder.

Weekly reports of the number of operating drilling rigs give an indication of the demand for cemented carbide components used by industry to explore for or produce oil and natural gas. During 2000, the trend in the number of rigs that operated in the United States continued the increase that began in April 1999. The lowest weekly count during 2000 was 755 in late January and the highest count was 1,114 in late December. In 2000, the average number of operating rigs in the United States increased 47% to 918, as compared with the 625 operating rigs in 1999 (Baker Hughes Inc., 2001, North American rig counts, accessed January 10, 2001, at URL http://www.bakerhughes.com/investor/rig/rig_na.htm).

In 2000, total consumption of tungsten scrap by U.S. processors and consumers was 5,120 t of contained tungsten, which was a 3% increase from the 4,980 t consumed in 1999.

Prices

Most published prices for ammonium paratungstate and tungsten concentrates significantly increased during the second half of 2000. The increase was the result of continued efforts by China, the world's largest tungsten supplier, to reform its industry (see China section of this report). Specifically, tighter control on exports of ammonium paratungstate was cited as the reason for increased prices (Metal Bulletin, 2000a, b, c). Ammonium paratungstate prices reported by Metal Bulletin began to increase in July. Metal Bulletin's annual average of high and low prices for ammonium paratungstate in the U.S. market was $66 per metric ton unit ($60 per short ton unit), 17% higher than that of 1999. Platt's Metals Week's U.S. price for ammonium paratungstate began to increase in September. Platt's annual average of high and low prices was $64 per metric ton unit ($59 per short ton unit), 13% higher than that of 1999. Annual average prices of ammonium paratungstate are listed in table 1.

The price of tungsten concentrates reported by Metal Bulletin began to increase in September. The average tungsten concentrate price reported by Metal Bulletin was $45 per metric ton unit, which was 12% higher than that of 1999. In contrast, the average of U.S. spot tungsten ore concentrate prices reported by Platt's Metals Week remained unchanged from that of 1999 at $47 per metric ton unit ($43 per short ton unit). Prices of tungsten concentrates are listed in tables 1 and 5.

Foreign Trade

The total tungsten content of U.S. exports was 2,870 t, approximately the same as the 2,880 t exported in 1999. As shown in tables 6 through 10, exports of tungsten carbide powder, tungsten ores and concentrates, tungsten wire, and other tungsten metal increased as compared with those of 1999, and exports of ammonium paratungstate, other tungstates, tungsten metal powders, tungsten waste and scrap, and wrought tungsten decreased.

The total tungsten content of U.S. imports was 8% lower than that of 1999. China, which continued to be the largest supplier of imported tungsten to the United States, provided 48% of all tungsten imports in 2000. The total tungsten content of imports from China decreased slightly in 2000 to 4,910 t, as compared with 5,000 t in 1999. Of the imports from China, 36% was ammonium paratungstate; 25%, tungsten oxides; 14%, concentrates; 8%, ferrotungsten; 5%, tungsten metal powders; 5%, tungsten waste and scrap; 3%, tungsten carbide powder; and the remainder, calcium tungstate, other tungstates, unwrought tungsten, and wrought tungsten.

Russia, which was the next largest supplier of imported tungsten materials to the United States, provided 17% of U.S. imports. In 2000, Russian imports were mainly tungsten oxide (49%), tungsten concentrates (23%), ammonium paratungstate (15%), tungsten waste and scrap (9%), ferrotungsten and tungsten metal powders (each 2%). Total imports from Russia decreased by 26% to 1,710 t of contained tungsten in 2000 compared with 2,300 t in 1999.

As shown in table 11, U.S. imports of tungsten ores and concentrates decreased by 17% in 2000 compared with those of 1999. Imports of concentrates originating from China resumed as a result of the termination of the 151% antidumping duty (see Legislation and Government Programs section of this report). In contrast, imports of ores and concentrates from Kazakhstan and Russia decreased significantly from those of 1999. In 2000, 95% of U.S. imports of ores and concentrates originated from six countries—China (29%), Portugal (21%), Bolivia (19%), Russia (17%), Peru (5%), and Rwanda (4%).

U.S. imports of ammonium paratungstate increased 18% as compared with those of 1999 (table 12). China continued to be the dominant supplier, providing 78% of U.S. ammonium paratungstate imports.

In 2000, imports of calcium tungstate, other tungsten chemicals, tungsten carbide powder, tungsten metal powders, unwrought tungsten, and wrought tungsten increased compared with those of 1999, but those of ferrotungsten, other tungstates, tungsten chlorides and tungsten waste and scrap decreased. Imports of tungsten oxides were at similar levels during the past 2 years (tables 13, 14).

Net import reliance as a percent of apparent consumption is used to measure the adequacy of current domestic production to meet U.S. demand. Net import reliance was defined as imports minus exports plus adjustments for Government and industry stock changes. Releases from stocks, including shipments from the NDS, were counted as part of import reliance, regardless of whether they were imported or produced in the United States. In 2000, net import reliance as a percent of apparent consumption was 63%. Because there was no U.S. mine production in 2000, this indicates that 63% of U.S. tungsten supply was from imports and stock releases and 37% was from scrap materials generated in the United States.

World Review

As shown in table 15, estimated world production of tungsten concentrates increased 4% as compared with that of 1999. China remained the leading world producer of tungsten concentrates. In addition to mine production and tungsten recovered from scrap, tungsten materials from stockpiles in Russia and other countries in the Commonwealth of Independent States (CIS) have been a significant component of world supply in recent years. Between 1992, when exports of tungsten from CIS countries first entered western markets, and mid-2000, an estimated 41,800 t of tungsten was exported from CIS countries. Information on the amount of tungsten that remained in CIS stockpiles and whether these materials would be released for export continued to be unavailable. During the past few years, however, the quantity of tungsten exported from the CIS has been decreasing (Kerr, 2001, p. 18-19; Maby, 2000,

Digitized by Google

p. 3-6; Martin, 2000; Trickett, 2000).

Austria.—Wolfram Bergbau und Hutten GmbH Nfg KG produced tungsten concentrates from the Mittersill scheelite mine in the Province of Salzburg. All these concentrates were converted to primary tungsten products at Wolfram Bergbau's Bergla tungsten processing plant in the Province of Steiermark.

Canada.—North American Tungsten Corp. Ltd. commissioned a mining and geological engineering firm to prepare a report on the company's tungsten assets and to review internal reports to evaluate the economic potential of restarting production from the company's CanTung Mine in southwestern Northwest Territories, near the border with Yukon Territory. On the basis of the firm's report, North American Tungsten felt that production from the CanTung Mine would provide the company with an attractive internal rate of return at current (September 2000) prices for tungsten concentrates. As a result of these findings, North American Tungsten and its marketing advisors began discussions with major consumers of tungsten concentrates for the purpose of entering into long-term supply contracts and with investment bankers (North American Tungsten Corp. Ltd., 2001c, d).

China.—The Chinese Government continued to reorganize its nonferrous metals industry. In July, the Government decided to dissolve the centrally controlled holding company China Rare Metals and Rare Earth Group Corp. (CRRC) and to transfer the management of its mines, plants, and research institutes to local governments. Management of the tungsten mines formerly controlled by Tungsten Mining Corp., which was a subgroup of CRRC, was transferred to Jiangxi, Hunan, and Guangdong Provinces. The assets and equity of China Tungsten & Cemented Carbide Industry Corp. (CTCCC), another subgroup of CRRC, and China Tungsten & Advanced Materials Corp., which was CTCCC's holding company, were transferred to the provinces of Hunan, Sichuan, and Hainan, where the assets were located. CTCCC consisted of Zhuzhou Cemented Carbide Works, Zigong Cemented Carbide Co., and Jinhai Industry Co. China Tungsten & Advanced Materials Corp. was a listed company on the domestic stock exchange formed by combining partial assets from Zhuzhou and Zigong (Juqiu, 2000).

After the transfer of the tungsten enterprises, the Chinese Government planned to continue to take action to make full use of its tungsten resources. The Government planned to continue to control the export of tungsten materials from China by imposing quotas on products such as ammonium paratungstate, tungsten concentrates, and tungsten oxides; by encouraging the export of value-added downstream tungsten products; and by giving priority to key enterprises of metallurgy, processing, and trade when granting export licenses. The Government planned to continue to control total tungsten production by closing mines that were running out of resources; by banning mines operating without licenses; by ordering tungsten metallurgical facilities that used outdated processes, that wasted resources, or that caused environmental pollution to make improvements or cease operating; and by allowing plants with poor management and debts surpassing their assets to go bankrupt. The Government would no longer directly control the enterprises. Rather, it planned to focus on formulating laws, regulations, and industrial policy; on giving guidance on production and marketing; on establishing an orderly market; and on promoting the sustained development of the Chinese tungsten industry. The China Non-Ferrous Metals Industry Association was established to take on some responsibilities for administration, to participate in developing regulations and standards for the industry, and to coordinate relationships between industries and between Government and individual enterprises (Juqiu, 2000).

Czech Republic.—Hydrometalurgicke Zavody, a.s. (HMZ) produced tungsten metal powders, tungsten carbide powders, cobalt sulfate, and other chemical products at its plant in Bruntál. The plant used ammonium paratungstate and sintered cemented carbide scrap as feed. In August, Osram GmbH of Munich, Germany, announced that it had signed a letter of intent to purchase HMZ (Šarman, 1999; Osram Sylvania Inc., 2000).

Portugal.—Beralt Tin & Wolfram S.A., an Avocet subsidiary, expanded production from the Panasqueira Mine (Avocet Mining plc, 2000a).

Russia.—According to the State Statistics Committee, Russian production of metallic tungsten in 2000 was 90% of that of 1999 (Interfax International Ltd., 2001).

During the year, efforts were underway to rehabilitate the Orlovsky GOK tungsten concentrator in Chita oblast in eastern Siberia. Recommissioning of the concentrator, which had been idle since 1994, was to occur in March or April 2001. Production of tungsten concentrates at full capacity levels was not anticipated to occur before 2002. The plant was to process locally mined ores (Interfax International Ltd., 2000).

Vietnam.—Tiberon Minerals Ltd. of Calgary, Alberta, Canada, explored the Nui Phao exploration license area 80 kilometers north of Hanoi. In September, the company began a drilling program to test tungsten-gold-copper-bismuth-tin mineralization in the Da Lien prospect. Initial results from one drill core showed tungsten grades similar to those at deposits currently being mined in China, Austria, and elsewhere. The company planned to expand its exploration activities to three additional mineralized targets within the license area (Tiberon Minerals Ltd., 2000).

Outlook

Demand for tungsten tends to follow general economic conditions. Future consumption of tungsten in cemented carbides, which is the largest end-use sector, will depend on the performance of the following industries: automotive and aircraft production, construction, mining, oil and gas drilling, and semiconductor and other manufacturing. Some recent developments in uses for tungsten include the shift from lead to tungsten for military and recreational ammunition and the use of tungsten by the sporting goods industry to make golf clubs and golf ball cores. The consumption of tungsten to produce 5.56 millimeter "green ammunition" for the military was forecast to grow from nearly zero in 2000 to between 450 t and 800 t of tungsten in 2005 (Middleton, 2000, p. 22).

World tungsten supply will continue to be dominated by Chinese production and exports. Beginning in 1999, the Chinese Government took several steps to control the release of tungsten to the market, which resulted in significant increases in the prices of ammonium paratungstate and tungsten concentrates during the latter half of 2000. Higher prices are expected to encourage an increase in the production of tungsten concentrates outside China. For example, in Bolivia, Empresa Minera Urania S.A. began to increase production in 2001 and planned to reopen two closed mines; International Mining Co. planned to increase tungsten production from its La Chojlla tungsten-tin operation; and Empresa Minera Himalaya Ltda. entered into an agreement with North American Tungsten to study the feasibility of developing a tungsten-tin deposit in

Digitized by Google

Murillo and Sadyumyai Provinces. In Canada, North American Tungsten continued to advance its plans to reopen the Cantung Mine and in 2001 signed a concentrate sales and loan agreement with Osram Sylvania and Sandvik AB (Metal Bulletin, 2001; North American Tungsten Corp. Ltd., 2001a, b).

VANADIUM

By Robert G. Reese, Jr.

Domestic survey data and tables were prepared by Adam A. Wario, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

In 2000, all U.S. vanadium production was from various industrial waste streams. Fewer than 10 firms, primarily in Arkansas, Louisiana, Texas, and Utah, processed materials such as vanadium-bearing iron slag, fly ash, petroleum residues, and spent catalysts to produce vanadium pentoxide, ferrovanadium, and vanadium metal. Recycling of vanadium was negligible; only small quantities of vanadium-based catalysts and vanadium-aluminum alloy were recycled.

Vanadium consumption in the United States decreased for the third consecutive year. Metallurgical applications in which vanadium was used as a minor alloying element with iron, steel, and titanium remained the dominant use and accounted for more than 90% of domestic consumption. The largest nonmetallurgical use for vanadium was in catalysts.

Six countries recovered vanadium from ores, concentrates, slag, or petroleum residues (table 7). China, Russia, and South Africa were the leading nations in vanadium production. In four of the five foreign countries, vanadium production was primarily a byproduct of iron mining and processing.

The U.S. Geological Survey (USGS) estimates that the vanadium reserve base is more than 27 million metric tons, a sufficiently large supply that by itself can satisfy the market for several hundred years at the present rate of consumption. Additionally, the expected increase recovery of vanadium from spent catalyst, fly ash, and petroleum residues will extend the viability of the reserve base significantly.

Legislation and Government Programs

The U.S. Department of Commerce (DOC) conducted an expedited review of the antidumping duties on Russian ferrovanadium and nitrided vanadium. The DOC found that the antidumping duties should be maintained. The duties ranged from 3.75% to 108%, depending on the producing company (Ryan's Notes, 2000a).

The U.S. International Trade Commission decided in September to conduct a full review of the antidumping duties on Russian ferrovanadium and nitrided vanadium (Ryan's Notes, 2000b). A ruling was expected in 2001.

Production

Near midyear, CS Metals of Louisiana LLP commissioned a new plant in Convent, LA (Metals Week, 2000). The plant will process spent petroleum catalysts and at full capacity is expected to recover nearly 2,300 metric tons (t) per year of vanadium pentoxide, molybdenum oxide, and possibly some nickel.

Consumption

In 2000, domestic vanadium consumption was 3,520 t. Although vanadium has many uses, metallurgical applications account for essentially all domestic consumption. Most vanadium is consumed in the form of ferrovanadium, which is used as a means of introducing vanadium into steels where it gives additional strength and toughness. Ferrovanadium is available as alloys containing 45% to 50% and 80% vanadium. The 45% to 50% grade is produced from slag and other vanadium-containing materials by the silicothermic reduction of vanadium pentoxide. Most of the 80% grade is produced by the aluminothermic reduction of vanadium pentoxide in the presence of steel scrap or by direct reduction in an electric arc furnace. Vanadium steels can be subdivided into microalloyed

Vanadium in the 20th Century

Metallurgical research near the end of the 19th century had shown the benefits of adding vanadium to tool steels and machinery for added toughness and fatigue resistance. However, vanadium was not an important commercial metal in the early 20th century because it was relatively rare and therefore expensive as well as difficult to produce in a pure form. In 1901, the United States produced approximately 340 metric tons of ore containing uranium and vanadium primarily from mining operations in Colorado. The first commercial production of ferrovanadium occurred domestically in 1907.

The commercial importance of vanadium was established during the first third of the century. Discovery of high-grade deposits in Namibia, Peru, and Zambia, along with additional development of the deposits on the Colorado Plateau in the Western United States, did much to ensure a sufficient supply of vanadium. Metallurgical progress was also being made during this period in the production of ferrovanadium. Simultaneously, commercial uses for vanadium-containing steels, such as in automobiles and armor plating, were being developed. Among the nonmetallurgical applications developed during this period was the use of vanadium pentoxide as a catalyst in the production of sulfuric acid. This type of catalyst was introduced into the United States in 1926 and gradually replaced platinum.

Vanadium uses changed little during the century. In 2000, metallurgical uses still dominated, accounting for more than 90% of domestic vanadium consumption. The source of vanadium supplies, however, changed significantly. Rather than recovering vanadium from ores as was done during the first half of the century, such materials as vanadium-bearing iron slag, fly ash, petroleum residues, and spent catalysts were processed to produce vanadium pentoxide, ferrovanadium, and vanadium metal.

Digitized by Google

or low-alloy steels, which generally contain less than 0.15% vanadium, and high-alloy steels, which contain as much as 5% vanadium. Nonmetallurgical applications include catalysts (which is the dominant use), ceramics, vanadium chemicals, and electronics.

The USGS derived vanadium consumption data from a voluntary survey of domestic consuming companies. For this survey, more than 80 vanadium companies were canvassed on a monthly or annual basis. Consumption data reported in tables 1 and 2 contain estimates for nonrespondents.

Prices

In 2000, the domestic price for ferrovanadium, as published in Metal Bulletin, ranged from $3.85 to $6.60 per pound, a wider range than the $4.35 to $6.25 range reported for 1999. The price reached its high in March and declined steadily throughout the remainder of the year. The lowest price was reported in December. The European ferrovanadium price recorded its high for the year in March and its low in January. The European price ranged from $7.45 to $13.50 per kilogram compared with $7.45 to $13.70 in 1999.

Metal Bulletin's published price for domestic vanadium pentoxide ranged between $1.25 and $2.65 per pound in 2000. The price peaked in March and steadily declined throughout the year. In 1999, Metal Bulletin's vanadium pentoxide price ranged from $1.25 to $2.90 per pound.

World Review

Nearly all the world's supply of vanadium is from primary sources. Six countries recovered vanadium from ores, concentrates, slag, or petroleum residues (table 7). The largest vanadium-producing nations remained China, Russia, and South Africa, with production primarily a byproduct of iron mining and processing. Japan and the United States were believed to be the only countries to recover significant quantities of vanadium from petroleum residues.

Recycling of vanadium was negligible. Its major use was as a minor element in iron, steel, and titanium-bearing alloys from which it is not extracted when those metals are recycled. Only small quantities of vanadium-based catalysts and vanadium-aluminum alloy were processed to recover vanadium.

In October, Precious Metal Australia Ltd. sold its 40% interest in the Windimurram vanadium mine to its joint venture partner Xstrata AG (American Metal Market, 2000). Precious Metal Australia retained a 15% net profit interest in the mine.

Outlook

In the near term, the major factor affecting the vanadium market will be the demand for steel. Longer term however, the consumption of vanadium will probably increase owing, in part, to the need for stronger and lighter steels and, in part, to the demand created by new applications, such as the vanadium battery. As in the United States, worldwide demand for vanadium is expected to be closely and directly related to the demand for steel.

VERMICULITE

By Michael J. Potter

Domestic survey data and tables were prepared by Nicholas Muniz, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Vermiculite is a hydrated magnesium-aluminum-iron silicate. Flakes of raw vermiculite concentrate are mica-like in appearance and contain water molecules within their internal structure. When the flakes are heated rapidly at a temperature of 900° C or higher, the water flashes into steam, and the flakes expand into accordion-like particles. The color, which can range from black and various shades of brown to yellow for the raw flakes, changes to gold or bronze. This expansion process is also called exfoliation, and the resulting lightweight material is chemically inert, fire resistant, and odorless. In lightweight plaster and concrete, vermiculite provides good thermal insulation. Vermiculite can absorb such liquids as fertilizers, herbicides, and insecticides, which can then be transported as free-flowing solids (Harben and Kuzvart, 1996).

Production

Domestic production (sold or used) data for vermiculite were collected by the U.S. Geological Survey (USGS) from two voluntary surveys—one for mine/mill operations and the other for exfoliation plants. Of three mine/mill operations, data were obtained from one. Output for the two nonrespondents was estimated based on previous years' production levels and estimates

Because there have only been three U.S. mining operations (two companies) of vermiculite concentrate in recent years, vermiculite data collected by the USGS are proprietary and must be withheld. However, according to Moeller (2001, p. 65), estimated U.S. output in 2000 was about 150,000 metric tons (t) (table 1). The two U.S. producers of vermiculite concentrate were W.R. Grace & Co., from its operation at Enoree, SC; and Virginia Vermiculite Ltd., with operations near Woodruff, SC, and in Louisa County, VA.

Vermiculite concentrate was shipped to exfoliating plants for conversion into lightweight material. Output of exfoliated vermiculite sold or used in 2000, using partly estimated data, was about 165,000 t (table 1). Domestic production of exfoliated vermiculite sold or used was by 13 companies operating 19 plants in 10 States (table 2). Of the 19 known exfoliation plants, 9, or 47%, responded. The nine operations produced 42% of the sold or used vermiculite listed in tables 1 and 3. Data for the remaining operations were estimated from previous years' production levels. States that produced exfoliated vermiculite, in descending order of output sold and used, were South Carolina, Ohio, Arizona, Pennsylvania, New Jersey, Arkansas, Florida, Illinois, Texas, and New Mexico.

Stansbury Holdings Corp. faced some unanticipated circumstances at its vermiculite operation at Dillon, MT. These included forest fires, the onset of a harsh winter, and mechanical breakdowns at its vermiculite mill. Also, the company's Los Banos, CA, exfoliating plant was facing new, more restrictive State air emissions standards. Consideration was being given to locating the Los Banos plant to another California location or to Nevada or Montana (Stansbury Holdings Corp., May 15, 2001, Letter to shareholders, accessed June 27, 2001, at URL http://www.stansburyholdings.com/shareholder_letters/may2000. html).

Consumption

Horticultural and other related applications, such as soil conditioning and free-flowing fertilizer carrier medium, continued to be major end uses of vermiculite. In soil conditioning, vermiculite particles retain moisture and nutrients, releasing them gradually to plant roots. The air spaces improve aeration of soil and create passageways for drainage (GTG Hydroponics, [undated], Soils and soil amendments, accessed August 21, 2001, at URL http://www.gtghydroponics.com/soil.htm). One supplier was offering, for example, a number of horticultural mixes that varied in composition but fell within the composition range of 10% to 55% Canadian sphagnum peat moss, 10% to 65% vermiculite, 5% to 20% perlite, 0% to 25% oak bark, and 0% to 60% pine bark. Uses for these products included seed starting, cutting propagation, and provision for

Vermiculite in the 20th Century

Vermiculite in the United States was first produced in small quantities in the mid-1920s. By 1936, the first year that vermiculite output was recorded by the U.S. Bureau of Mines, production of vermiculite concentrate had reached about 15,400 metric tons. The major use for exfoliated (expanded) vermiculite was for heat, cold, or sound insulation. It was used loose as a filler in the walls of houses and in water heaters, fire safes, stoves, furnaces, and refrigerators. It also served as a lightweight aggregate in insulating plaster, concrete, and other materials, where insulating and sound-deadening properties and low specific gravity were of value. Output of vermiculite concentrate in the United States reached a high of about 331,000 tons in 1973.

In 2000, U.S. output of vermiculite concentrate was an estimated 150,000 tons. Insulation and agricultural uses (such as horticulture and soil conditioning) accounted for about 80% of the usage of the exfoliated vermiculite product. U.S. imports of vermiculite were about 59,000 tons; South Africa supplied about 74%, and China, about 23%. South Africa had the world's largest output of vermiculite during the 1990s, and in 2000, it produced about 209,000 tons.

Digitized by Google

aeration, percolation, and nutrient retention characteristics in horticulture and some landscape applications (The Scotts Company, Summer 2001, Product guide—Soil mixes & amendments, accessed July 31, 2001, at URL http://www.scotts.com/professionalhoriculture/SoilMixesAmendments.cfm).

Another application of vermiculite was use beneath above-ground swimming pools as a pool cushion. It provides a soft, level surface that protects the vinyl liner from sharp objects. Vermiculite also can be mixed with portland cement to form an insulating monolithic porous concrete base for use beneath vinyl inground swimming pools. The base protects pools from being damaged by changes in the water table and hydrostatic pressure (The Schundler Co., [1994]).

Prices

Published prices for vermiculite serve as a general guide only because of variations in source, quantity, application, and other factors. Prices for raw (unexpanded) U.S. vermiculite concentrate, bulk, ex-plant were about $143 to $220 per metric ton, depending on particle size. For imported South African crude vermiculite, bulk, f.o.b. barge, U.S. Gulf Coast, prices ranged from $187 to $243 per ton (Industrial Minerals, 2000b).

The average value of U.S. exfoliated vermiculite sold or used by producers, using partly estimated data, was $322 per metric ton (table 1) and was a composite value including both U.S. and imported material.

Foreign Trade

Trade data for vermiculite concentrate are not collected as a separate category by the U.S. Census Bureau but are included within the basket category "vermiculite, perlite, and chlorite, unexpanded" under tariff code 2530.10.0000. According to Moeller (2001), U.S. exports of vermiculite concentrate in 2000 were about 5,000 t (table 1) and were believed to be shipped primarily to Canada. Total U.S. imports of vermiculite in 2000 were about 59,000 t (Port Import/Export Reporting Service, data printout, 2001). South Africa supplied about 74% of the tonnage, and China, 23%.

World Review

In Western Europe, the United Kingdom was the major consumer of vermiculite. The largest end use in Western Europe was for building boards, which were essentially of two types. One type was produced using a wet slurry manufacturing process; the other type was made using a binder such as metal silicate or equivalent (Ellicott, 2000).

A number of companies in Western Europe produced exfoliated vermiculite for the horticultural market. The insulation market included loose-fill insulation and insulation shapes for uses that included secondary insulation in such industrial installations as aluminum smelters (Ellicott, 2000).

Canada.—Normiska Corp., Mississauga, Ontario, signed an agreement to acquire VIL Vermiculite, Inc., for about $1.8 million. VIL's assets included manufacturing facilities for horticultural grades of vermiculite and perlite in Lachine, Quebec. Normiska's product lines included sphagnum peat moss, pine bark mulches, and composts (Industrial Specialties News, 2000).

South Africa.—Palabora Mining Co. Ltd. is the world's largest supplier and exporter of vermiculite from its operation in the northern Transvaal. Material is exported worldwide (Russell, 2000). The company formerly named Natkruit Vermiculite Mine (Pty.) Ltd., which is located north of Pietersburg, was purchased by an offshore holding company and became known as Natkruit Mine. Plans called for an increase in output to 24,000 metric tons per year (t/yr) by 2001 from 18,000 t/yr. Natkruit was exporting vermiculite largely to the refractory, horticultural, and fire protection industries of Europe (Industrial Minerals, 2000a).

Outlook

Although horticultural and related applications have been the largest end uses of vermiculite in the United States in recent years, other uses appear to be growing, including as an intumescent (swelling) material for use, for example, in gaskets. Another use is in coatings and binders (chemically delaminated vermiculites that form high-tensile-strength films). As finely ground material, vermiculite serves as a functional filler in coatings, construction materials, and friction brake applications (Moeller, 2001). Materials that compete with vermiculite in general include mineral wool, perlite, and polystyrene (Ellicott, 2000).

Although South Africa is the largest supplier of vermiculite, Australia, Brazil, China, and Zimbabwe have significant output. Production of the mineral in China was said to be increasing, and that country may become a major supplier in the future (Moeller, 2001).

WOLLASTONITE

By Robert L. Virta

Domestic survey data were prepared by Raymond I. Eldridge III, statistical assistant.

Wollastonite, a calcium metasilicate ($CaSiO_3$), has a theoretical composition of 48.3% calcium oxide and 51.7% silicon dioxide but may contain trace to minor amounts of aluminum, iron, magnesium, manganese, potassium, and sodium. It occurs as prismatic crystals that break into massive-to-acicular fragments. It is usually white, but also may be gray, brown, or red depending on its composition.

Wollastonite forms when impure limestones are metamorphosed (subjected to heat and pressure) or silica-bearing fluids are introduced into calcareous sediments during metamorphic processes. In both cases, calcite reacts with silica to produce wollastonite and carbon dioxide. Wollastonite also can crystallize directly from a magma that has an unusually high carbon content, but this is a more rare occurrence.

Deposits of wollastonite have been found in Arizona, California, Idaho, Nevada, New Mexico, New York, and Utah. These deposits also may contain calcite, diopside, garnet, idocrase, and quartz as minor components.

Wollastonite is used primarily in ceramics, friction products (brakes and clutches), metallurgy, paint, and plastics. Some of the properties that make it so useful are its high brightness and whiteness, low moisture and oil absorption, low volatile content, and the acicular nature of some wollastonite.

Production

Wollastonite has been mined commercially in California and New York. The California deposits, which are in Inyo, Kern, and Riverside Counties, were mined between 1930 and 1970. These operations were limited in size, producing only a few thousand metric tons per year for ceramics, decorative stone, paint, and mineral wool production.

Wollastonite deposits in New York have been mined for more than 50 years. Two companies currently are mining wollastonite: NYCO Minerals Inc., a subsidiary of Fording Inc., operates a mine in Essex County, and R.T. Vanderbilt Co. Inc. operates a mine in Lewis County. The NYCO Minerals deposit contains wollastonite, garnet, and diopside. Parts of the deposit are composed of up to 60% wollastonite. The ore is processed at the Willsboro plant where the garnet is removed by using high-intensity magnetic separators. NYCO also chemically modifies the surfaces of some of its wollastonite products to improve their performance. The R.T. Vanderbilt deposit in Lewis County consists primarily of wollastonite, minor amounts of calcite and prehnite, and trace amounts of diopside. The ore is processed at its Balmat plant where it is milled and air classified.

Domestic wollastonite production decreased from that of 1999. Much of the decrease occurred because NYCO Minerals began supplying powder-grade wollastonite to some of its North American customers from its operation in Sonora, Mexico, instead of its New York operation. This change permitted the company's New York operation to effectively increase its capacity for its higher value products and made better use of the company's ore reserves. Additionally, NYCO Minerals added a stirred-media grinding mill and new magnetic separators to its Willsboro plant and began pilot studies for pelletizing wollastonite fines (Fording Inc., 2000, p. 26-28). Although data collected by the U.S. Geological Survey are withheld to avoid revealing proprietary information, U.S. production was estimated to be on the order of 130,000 metric tons per year (t/yr) (Rieger, 2000).

Consumption

The use of wollastonite in the United States declined slightly from that of 1999. Sales probably were slightly lower for ceramic, metallurgy, and paint applications. Plastics markets,

Wollastonite in the 20th Century

Domestic mining of wollastonite has had a rather short history compared to many other mineral commodities. There was essentially no commercial mining of wollastonite in 1900. Small scale mining did not begin until the 1930s, and annual production was only on the order of a few thousand tons. Weathered wollastonite that looks like petrified wood was a popular product for landscaping. Wollastonite also was sold to the ceramics, mineral wool, and paint industries in small quantities. This level of production continued through the 1950s with all domestic production occurring in California. In the 1950s, a large wollastonite deposit was developed in New York, and large-scale production of wollastonite began in the United States. The high demand for housing following World War II resulted in the expansion of construction-related markets and provided a ready outlet for the increased production capacities. By 1960, U.S. wollastonite production and sales were about 35,000 metric tons; ceramics and paints were the major markets.

In 2000, production was estimated to be about 130,000 tons. Between 1960 and 1990, production and sales of wollastonite increased steadily as ceramic and paint markets expanded. Wollastonite sales also received a boost when the debate over the health risks posed by asbestos intensified during the 1970s and early 1980s. It was during this time that asbestos substitute markets, for which wollastonite was well suited, opened up. By 1990, production was estimated to be about 110,000 tons. In 2000, plastics comprised an estimated 37% of wollastonite sales, followed by ceramics (28%), metallurgical applications (10%), paint (10%), friction products (9%), and other applications (6%). Some other applications for wollastonite were abrasive wheel bond, adhesives, joint compounds, refractories, rubber filler, and welding rods. Wollastonite has been used as an asbestos substitute in such products as floor tiles, friction products, insulating board and panels, paint, plastics, and roofing products.

Digitized by Google

however, appear to have remained strong.

Major domestic uses of wollastonite were in plastics (37%), ceramics (28%), metallurgy (10%), paint (10%), friction products (9%), and miscellaneous (6%) (Industrial Minerals, 1999). Wollastonite also was used in adhesives, joint compounds, refractories, rubber, and wallboard applications.

In ceramics, wollastonite decreases shrinkage and gas evolution during firing, increases green and fired strength, permits fast firing, and reduces crazing, cracking, and glaze defects. In metallurgical applications, wollastonite serves as a flux for welding and to protect the surface of the molten metal during the continuous casting of steel. As a filler in paint, it reinforces the paint film, acts as a pH buffer, improves its resistance to weathering, reduces pigment consumption, and acts as a flatting and suspending agent. In plastics, it improves tensile and flexural strength, reduces resin consumption, and improves thermal and dimensional stability at elevated temperatures. Surface treatments are used to improve the adhesion between the wollastonite and the polymers to which it is added. As a substitute for asbestos in floor tiles, friction products, insulating board and panels, paint, plastics, and roofing products, wollastonite is resistant to chemical attack, inert, stable at high temperatures, and a good reinforcer.

Prices

Prices per metric ton for domestically produced acicular wollastonite, ex-works, were $209 for 200 mesh, $258 for 325 mesh, and $284 for 400 mesh. The price per ton, ex-works, for acicular, high-aspect-ratio wollastonite was $351 and for ground (10-micrometer) wollastonite was $694. Prices per ton for wollastonite, free on board, in bulk, were $209 for 200 mesh and $253 for 325 mesh (Industrial Minerals, 2000). Quoted prices should be used only as a guideline because actual prices depend on the terms of the contract between the seller and the buyer.

Foreign Trade

Foreign trade data were not available from the U.S. Census Bureau for wollastonite. Imports previously were estimated to be between 2,500 metric tons (t) and 5,000 t. The revised estimate is between 10,000 t and 12,000 t, mainly because NYCO Minerals began supplying some of its North American customers from its operation in Mexico. Imports from China also were believed to have increased in 2000 compared with those of 1999. Most of the imports are thought to be lower-value wollastonite grades. Some wollastonite also was imported from Finland and India. Exports were estimated to be between 5,000 t and 8,000 t in 2000.

World Review

Worldwide production of wollastonite was estimated to be between 500,000 t and 550,000 t in 2000. China again was an unknown factor with regard to wollastonite production and sales. Production estimates for China typically have been in the 200,000-t/yr to 300,000-t/yr range. One source estimated exports from China to be between 100,000 t/yr and 150,000 t/yr and domestic consumption to be 100,000 t/yr, placing production in the 200,000-t/yr to 250,000-t/yr range (Roskill Information Services Ltd., 1996, p. 18). Production for Finland, India, and Mexico was estimated to be 20,000 t, 100,000 t, and 75,000 t, respectively. With the closure of the only Canadian producer, production from Canada was estimated to be at most a few hundred tons. Small tonnages probably also were produced in Chile (reported as 270 t in 1996), Namibia (reported as 347 t in 1999), North Korea, Pakistan, South Africa (reported as 200 t in 1999), and Turkey.

Canada.—The board of directors of Orleans Resources Inc. suspended production at the Lac St.-Jean plant in July 2000. A build-up of inventory, the company's financial situation, and lack of a partner prompted the action. The company planned to meet client needs from inventory (Orleans Resources Inc., 2000). Orleans Resources also hired the consulting firm KPMG International to locate a business partner for Orleans or conduct a sale of the company's assets (North American Minerals News, 2000).

Outlook

The decline of the U.S. economy, which began in 2000, probably will continue to hamper sales in the United States, causing a stagnation or slight decline in sales and consumption. Markets most likely to be affected will be in ceramics, metallurgy, and paint. Sales for friction products also may decline slightly. Decreases such as these would be expected during an economic slowdown with associated downturns in housing starts (ceramic and paint markets), automobile sales (friction products), and steel output (metallurgical applications). The most promising market is plastics; sales should increase in the coming years. Despite economic slowdowns faced by some other countries, worldwide sales of wollastonite should increase slightly as more durable goods are required for growing populations.

ZEOLITES

By Robert L. Virta

Domestic survey data and tables were prepared by Raymond I. Eldridge III, statistical assistant.

Zeolites are hydrated aluminosilicates of the alkaline and alkaline-earth metals. About 40 natural zeolites have been identified during the past 200 years; the most common are analcime, chabazite, clinoptilolite, erionite, ferrierite, heulandite, laumontite, mordenite, and phillipsite. More than 150 zeolites have been synthesized; the most common are zeolites A, X, Y, and ZMS-5. Natural and synthetic zeolites are used commercially because of their unique adsorption, ion-exchange, molecular sieve, and catalytic properties.

Natural Zeolites

Commercial zeolite deposits in the United States are associated with the alteration of volcanic tuffs in alkaline lake deposits and open hydrologic systems. Commercial deposits in the United States are in Arizona, California, Idaho, Nevada, New Mexico, Oregon, Texas, Utah, and Wyoming. Zeolites in these deposits are chabazite, clinoptilolite, erionite, mordenite, and phillipsite. Other components, such as orthoclase and plagioclase feldspars, montmorillonite, opal, quartz, and volcanic glass, are present in some deposits.

Production.—Conventional open pit mining techniques are used to mine natural zeolites. The overburden is removed to allow access to the ore. The ore may be blasted or stripped for processing by using front-end loaders or tractors equipped with ripper blades. In processing, the ore is crushed, dried, and milled. The milled ore may be air-classified as to particle size and shipped packaged in either bags or bulk. The crushed product may be screened to remove fine material when a granular product is required, and some pelletized products also are produced. Producers also may modify the properties or blend their zeolite products with other materials prior to sale to improve their performance.

Domestic data for natural zeolites were collected by means of a voluntary survey of the domestic mining industry. Survey forms were sent to nine companies with responses accounting for approximately 90% of the production and consumption data.

Eight companies mined natural zeolites in the United States in 2000. Three other producers did not mine zeolites during the year but sold from stocks or purchased zeolites from other producers for resale (table 1). Chabazite was mined in Arizona and Nevada; clinoptilolite was mined and processed in California, Idaho, Nevada, New Mexico, Oregon, Texas, and Wyoming; and mordenite was mined in Nevada. The largest producing State was New Mexico. Total domestic production of zeolites was estimated to be 41,800 metric tons (t) compared with an estimated 43,000 t in 1999.

GSA Resources, Inc., announced plans to acquire or collaborate with other suppliers of specialty minerals. The company's intent was to produce entire systems, rather than single products, that can be used for remediation of hazardous wastes, odor control, and other sorption applications (North

Zeolites in the 20th Century

The mining of zeolites is a recent activity compared to many other mineral commodities. In 1900, there was no commercial mining of natural zeolites. Sustained mining of natural zeolites did not begin until the early 1970s. The delay in the start of zeolite mining can be attributed mainly to the fact that, prior to the 1950s, natural zeolites were originally considered to be mineralogical curiosities that filled vugs and fractures in igneous rocks, and commercial deposits were not known. In the late 1950s, large deposits of zeolite-rich volcanic tuffs were discovered in the western United States. Between 1950 and the mid-1980s, many large mining and petroleum companies conducted exploration programs. While these programs uncovered additional reserves, markets for natural zeolites did not develop as anticipated, and only a few hundred tons of zeolites were mined annually through the mid-1970s. By the mid-1980s, annual production and sales of natural zeolites were still below 10,000 metric tons, so the major companies withdrew from the industry. Companies better suited to small-scale mining then stepped in and have slowly developed the natural zeolite market into the small yet sustainable industry that exists today.

In 2000, there were 41,800 tons of natural zeolites mined in several States in the Western United States. This is about triple the production and sales in the 1980s but less than the peak production and sales of 53,000 tons attained in 1994. Even with the short mining history, the industry has shifted its focus. Initially, zeolites were treated as bulk commodities, with producers seeking large volume markets. Pet litter applications, for which zeolites were well suited, became the mainstay of the industry, representing more than 50% of sales of natural zeolites annually in the mid-1980s. Producers, however, realized that low-value bulk sales of zeolites could not sustain the industry forever and began developing value-added applications. As a result, pet litter markets, while still important, commanded a far smaller share of the overall market in 2000, with the growth of horticultural (soil conditioners and fertilizer carriers), animal feed, waste water treatment, desiccant, water purification, and gas absorbent markets.

Digitized by Google

American Minerals News, 2000b). Centre Capital rescinded its purchase of American Absorbents Natural Products, Inc. (AANPI), from Equitable Assets Inc. The transaction was to have involved the exchange of one million shares of Centre Capital stock valued at more than $11.3 million. AANPI, one of the larger producers of zeolite-based cat litter, still holds its zeolite deposit in Oregon (Moore, 2000; North American Minerals News, 2000c).

Consumption.—An estimated 30,900 t of natural zeolites was sold in 2000 in the United States compared with an estimated 35,000 t in 1999. Natural zeolites were sold for, in decreasing order by tonnage, pet litter, animal feed, horticultural applications (soil conditioners and growth media), wastewater cleanup, odor control, fungicide or pesticide carriers, desiccants, gas absorbents, catalysts, water purification, aquaculture, and oil absorbents. Pet litter, animal feed, and horticultural applications accounted for more than 70% of the domestic sales tonnage. Sales to individual markets did not change significantly compared with those of 1999.

Prices.—Prices for natural zeolites varied with zeolite content and processing. For industrial or agricultural applications, prices ranged from $30 to $70 per metric ton for granular products down to 40 mesh and from $50 to $120 per ton for finer (-40 to -325 mesh) ground material (Holmes, 1994, p. 1150-1151). For such products as pet litter, fish-tank media, or odor control applications, prices ranged from $0.50 to $4.50 per kilogram. Quoted prices should be used only as a guideline, because actual prices depend on the terms of the contract between seller and buyer.

Foreign Trade.—Although trade data for natural zeolites are not available, imports of natural zeolites were estimated to be less than 100 t, and exports were estimated to be less than 200 t in 2000. The bulk of the international trade appears to be in synthetic zeolites.

World Review.—Worldwide production of natural zeolites was estimated to be between 3 million and 4 million metric tons (Mt) based on reported production by some countries and production estimates published in trade journals. Estimates for individual countries were China, 2.5 Mt; Cuba, 500,000 to 600,000 t; Japan, 140,000 to 160,000 t; the United States, 41,800 t; Hungary, 10,000 to 20,000 t; Slovakia, 12,000 t; Georgia, 6,000 t; New Zealand, 5,000 t; Greece, 4,750 t; Australia, Canada, Italy, and other republics of the former Soviet Union, 4,000 t each; Bulgaria, 2,000 t; and South Africa 1,000 to 2,000 t. Small amounts of natural zeolites also were produced in Argentina, Germany, and Indonesia.

Australia.—Talon Resources NL announced plans to develop horticultural and environmental products that were zeolite-based. The company has made its first sales to the agricultural market. The company also commissioned a zeolite production plant in Duaringa, Queensland (Countryman, 2000).

Canada.—C_2C Mining Corp. completed an animal feed study with Klok Feeds, which raises 40,000 feeder hogs annually. The zeolite was mixed with the feed ingredients, replacing the bentonite and lignite sulfinate binders normally used. The study revealed that the addition of zeolites in the feed reduced odors and increased feed conversion rates. C_2C also worked with Amoco Canada Petroleum Co. Ltd. to conduct soil remediation tests using zeolites. Plans are to bring the C_2C deposit into production by the end of 2001. C_2C also signed an agreement with Zeo-Tech Enviro Corp., which holds the rights to a zeolite deposit near Princeton, British Colombia. C_2C will hold a 25% interest in the zeolite holdings and a new processing plant that is expected to be constructed by the end of 2001. In return, Zeo-Tech Enviro will have access to C_2C's patented processing methods for specialty zeolite products and will receive a 25% share of C_2C's zeolite properties near Kentville, Nova Scotia (North American Minerals News, 2000a).

Ukraine.—The Government of Ukraine has placed a 25% share of Zatissyansky Chemical Plant up for sale. The Government owned about 60% of the company. Zatissyansky Chemical is the only Ukrainian producer of zeolite powders (Industrial Minerals, 2000).

Current Research and Technology.—Researchers examined the exchange of sodium by cesium and strontium in analcime-bearing assemblages. The exchange was conducted at 250° C to 300° C and 39.7 to 85.8 bars of pressure in pure water and chloride solutions. A continuous solid solution between sodium and cesium and sodium and strontium did not occur. Thermodynamic calculations indicated that leaching would be minimized at about a pH of 8, suggesting that an analcime-albite-paragonite assemblage may act as a barrier to the migration of cesium and strontium from radionuclide-contaminated materials. This is an important consideration for underground storage of high-level radioactive wastes (Redkin and Hemley, 2000).

Synthetic Zeolites

Catalysts.—Lurgi GmbH designed a fixed-bed catalytic cracker that can be incorporated into a naphtha steam cracker system. The fixed-bed system converts olefins into propylene and ethylene. The system is reported to convert 60 weight percent of C_4 and C_5 components from the steam cracker directly to propylene. Pilot plant studies are planned by Linde Division, Union Carbide Corp., who licensed the process from Lurgi. The catalytic cracker uses ZMS-5 zeolite in a fixed bed at 500° C and 1 to 2 bars to make the conversion. Coking and polymer formation are reduced through the introduction of steam. Cycle times are several weeks, and anticipated zeolite life is 15 months (European Chemical News, 2000b).

The Institut Francais du Petrole developed a new zeolite-based isomerization catalyst. The catalyst is reported to increase paraxylene yield to 93% compared with 88% with typical mordenite-based catalysts. Pilot plant testing has shown that paraxylene yield losses were reduced by 40% to 50%. The system also can operate under milder operating conditions, reducing operating and capital costs (European Chemical News, 2000a).

Detergents.—There was an estimated 1.04 Mt of synthetic zeolite used worldwide in detergents in 1998. This represents the largest volume segment of the synthetic zeolite market. In the United States, demand for powder detergents has declined. Liquid detergents surpassed powder detergents for the first time in 1998. Powders are still preferred in Europe but have lost some popularity with the consuming public. The declining demand, coupled with additional capacity that came online in the early 1990s, has resulted in overcapacity in Japan, North

Digitized by Google

America, and Western Europe; projected growth in detergent uses in these markets is -1%, -2%, and 0.4%, respectively (LePree, 2000). In Western Europe, zeolites were estimated to account for 75% of the builder market for home laundry detergents with phosphates making up the remaining 25%. Builders are used to reduce water hardness. The decision to allow phosphate-based detergents to carry the European Union's "eco-label" resulted in market gains in 1999. Despite gains in Asia, phosphate-based detergents may be threatened by new legislation to remedy lake eutrophication, the process of excess nutrients promoting plant growth at the expense of animal life, in some regions in China. If demand for zeolite builders grows in China, plants in Southeast Asia will supply that market (Chemical & Engineering News, 2000b).

Molecular Sieves.—PQ Corp. announced that it would withdraw from the molecular sieve adsorbent market in 2000. The company cited excess supplies and consequent marginal returns for the withdrawal. PQ will continue to supply synthetic zeolites for adsorption and separation, detergents, and chemical and petrochemical applications (Walsh, 2000).

Tricat Zeolites GmbH constructed a new plant in Bitterfield, Germany, for manufacturing zeolites and sieves (European Chemical News, 2000d).

Current Research and Technology.—Demand for catalysts for petroleum refining is expected to increase at a rate of 1.9% per year between 1998 and 2003 as the demand for petroleum increases. One of the issues facing refiners is the reduction in the permissible sulfur content of gasoline. In 1999, the U.S. Environmental Protection Agency proposed reducing sulfur limits from 330 parts per million (ppm) to 30 ppm. Similarly, in Europe, proposed regulations will limit permissible sulfur content to 150 ppm in 2000 and 50 ppm in 2005. Emphasis is being placed on fluid catalytic cracking (FCC) units because FCC products contribute more than 90% of the sulfur in gasoline. Hydrocracking the FCC feed can reduce sulfur content but is expensive. Despite this, predictions were for growth in precious metals and zeolites for hydrocracking to increase. Another approach is to convert some of the sulfur species into forms that are more easily removed from gasoline. For example, catalysts that result in reaction pathways that lead to the formation of hydrogen sulfide would reduce sulfur in gasoline. Another approach is to develop catalysts that react with specific sulfur compounds that are difficult to remove from gasoline, such as benzothiophene. There also is a need to reduce olefin content of gasoline in response to new environmental regulations. Modified FCC catalysts and ZMS-5 zeolite have been used to control olefin content (European Chemical News, 2000c; Oil & Gas Journal, 2000a).

A mesoporous (large pore structure) zeolite catalyst has been developed by Haldor Topsoe Research Laboratories of Denmark for the epoxidation of cyclohexene. The zeolite structure contains titanium cations and, with the mesoporous structure, is chemically more active than conventional titanium-containing zeolite catalysts. The zeolite is prepared using an excess zeolite gel and a carbon matrix. The carbon is removed after synthesis by combustion (Chemical & Engineering News, 2000c).

A study was conducted on erosion of the FCC unit by FCC catalysts. FCC catalysts, typically composed of aluminum and silica, can erode portions of the FCC unit not properly protected by linings. Attrition resistance was one characteristic that was considered critical. Attrition-resistant particles resulted in generation of fewer fine particles and fewer sharp-edged, irregular particles that are created when larger particles fracture. Attrition of the catalyst can result in particle losses in some FCC units, while those units designed to minimize fines loss will experience an increase in particle bulk density. Sharp, irregular particles erode the FCC unit more rapidly than spherical particles. The study also showed that increased cyclone velocity magnifies attrition rates and is influenced by particle density and size. In general, higher particle densities and smaller sizes tended to reduce erosion rates (Oil & Gas Journal, 2000b).

Scientists take advantage of the rigid structure and the pores and channels of zeolites to control the reactions. The pores and channels define the size of the molecules that can form and diffusion rates within the structure and even cause selective orientation of the molecules within the structure so that only one face of a molecule can react (Chemical & Engineering News, 2000a). For example, scientists at Tulane University in New Orleans working with researchers at the University of British Columbia in Vancouver created a stable chiral zeolite structure by loading an existing zeolite structure (zeolite Y) with chiral organic molecules. Previously, researchers had unsuccessfully attempted to synthesize the chirally modified zeolite structures. The use of the modified zeolite structure resulted in a high stereoselectivity during the reaction process. Sodium in the Y zeolite was found to be critical. When cesium, lithium, and potassium were exchanged for the sodium, enantiomeric excesses decreased. The chirally-modified zeolite structure will be used to synthesize molecules that are normally difficult to form and also to produce odd-shaped and highly strained chemical species (Chemical & Engineering News, 2000d).

Research continued on the use of zeolites to remove nitrogen oxides (NO_x) from automobile exhaust. Chemists at the Catholic University of Leuven in Belgium, used the sodium variety of zeolite Y to absorb NO and NO_2 as dinitrogen trioxide (N_2O_3) from engines that use excess air to reduce carbon dioxide emissions. Barium oxides used in lean-burn engines work best with very low sulfur fuels. The zeolite Y absorbent is not affected by the presence of sulfur oxides, and the absorption process can be reversed. This suggests the possibility of recirculated trapped NO_x into the intake air so it can be converted to nitrogen gas during the combustion process (Chemical & Engineering News, 2000e).

Outlook

Market growth for natural zeolites will continue to be slow. Growth in the major market, pet litter, has been slight for the past few years and is not expected to increase significantly. Domestic sales of natural zeolites probably will be between 30,000 t to 35,000 t for the next few years. Pet litter probably will remain the largest market. As it has for the past few years, low-tonnage niche markets should offer opportunities for producers to introduce high-unit-value products, particularly for environmental applications. Markets for synthetic zeolites in the United States will slow. Detergents sales have stagnated

Digitized by Google

and possibly declined slightly in recent years. Sales in Europe also may slow as phosphate-based detergents regain acceptance. Possible growth can occur in China depending on the effectiveness of new legislation discouraging phosphate builder use. Projections for growth in the catalyst for petroleum refinery market are positive with the anticipated growth in demand for gasoline worldwide.

ZINC

By Jozef Plachy

Domestic survey data and tables were prepared by Aaron J. Poyer, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

In 2000, domestic zinc mine production, expressed in zinc content of ore, increased by nearly 2% from that of 1999, mainly due to increased production in Alaska and Missouri (table 1). On the basis of recoverable content and annual average U.S. price, the value of zinc mine production was estimated to be about $1 billion. Zinc was extracted from 19 mines in 6 States by 8 companies (tables 2, 3). For the 10th consecutive year, Alaska was the leading zinc mining State, followed by, in descending order, Tennessee, Missouri, and New York. In 2000, as in every year since the opening of the Red Dog Mine in 1989, U.S. mine production greatly exceeded smelter capacity (table 6), necessitating exports of concentrate. More than one-third of exports, which were supplied entirely by the Red Dog Mine, was trucked to the Trail smelter in Canada; the remaining two-thirds went mainly to Asian markets (table 14). Primary zinc metal production by the three primary smelters decreased by more than 5% in 2000 (tables 4, 6).

Apparent consumption of refined zinc metal in 2000 decreased nearly 2%, owing to the slowdown of the economy. Of the total refined zinc metal consumed in the United States, about one-half was used for galvanizing, followed by use in zinc-based alloys and in brass and bronze (table 11). Zinc compounds and dust were used principally by the agricultural, chemical, paint, and rubber industries.

The average U.S. producer price for refined zinc in 2000, which was based on the London Metal Exchange (LME) daily cash price plus premium, increased by about 5% to $1.13 per kilogram (51.15 cents per pound).

World production of zinc concentrate by 41 countries increased by about 9% in 2000, to more than 8.7 million metric tons (Mt). The largest producers were, in decreasing order of magnitude, China, Australia, Canada, Peru, and the United States (table 17). World smelter production increased by nearly 6%, to about 9 Mt. The largest producer of zinc metal was China, followed by Canada, Japan, Australia, the Republic of Korea, Spain, and the United States (table 18).

Legislation and Government Programs

In January 19, 2000, the U.S. Environmental Protection Agency (EPA) finalized the Clean Water Act (CWA) establishing national, technology-based effluent limitations and pretreatment standards for waste water discharges associated with the operation and maintenance of new and existing hazardous and nonhazardous landfill facilities regulated under the Resource Conservation and Recovery Act (RCRA). Because of an insufficient amount of contained biologically degradable organic material in the leachate of inorganic landfills, EPA concluded that the alternative technology of chlorination and use of granual activated carbon is as effective and economically achievable as the biological treatment of nonhazardous landfills containing biodegradable material. The proposed CWA limits zinc in nonhazardous landfills to a monthly average of 0.11 milligram per liter (mg/L) and a daily maximum limit of 0.20 mg/L. EPA estimated that the final CWA should remove about 400 metric tons per year (t/yr) of pollutants at an estimated annual cost of $7.6 million (U.S. Environmental Protection Agency, 2000).

In 1998, the U.S. Geological Survey conducted a study to determine how much copper, gold, lead, silver, and zinc is undiscovered in the United States not more than 1 kilometer (km) below the Earth's surface. These commodities were chosen because they are the most valuable metals, after iron and aluminum, and because they usually occur together in nature. Partially based on the 1973 study by Wedow and others (1973), the estimate of the amount of zinc in undiscovered deposits ranged from greater than130 Mt at a 90% probability to greater than 290 Mt at a 10% probability. Nearly 40% of the zinc was

Zinc in the 20th Century

By the beginning of the 20th century, the United States was the leading world zinc metal producer, a position held for most of the next 70 years. Mostly zinc sulfide (sphalerite) ore was crushed, washed, and subjected to gravity separation. About 65% of zinc metal was produced in Missouri, with smaller quantities produced in Colorado and New Jersey (from non-sulfide ore). In 1900, domestic production of zinc metal reached about 112,400 metric tons, 18% of which was exported. Consumption reached 90,200 t, about 50% of which was used in galvanizing, 26% was used in brass, and 17% was used to produce sheet metal.

During the next 100 years, new beneficiation processes, mainly flotation, increased zinc metal recovery up to 87%. Advancements in retort smelting and the introduction of electrolytic processing increased efficiency of zinc metal production while reducing air pollution. Increasingly stringent environmental laws, however, made the building of new domestic smelters more costly. Consequently, by 2000, the United States had only three primary smelters producing 228,000 tons of zinc metal. With another 143,000 tons of secondary zinc, U.S. production accounted for only about one-fourth of its consumption. The remaining zinc for U.S. consumption was imported, mainly from Canada. The United States was the second largest consumer of zinc in the world, with a cumulative total use of 1.32 million tons of zinc metal. Of that total, about 57% was used in galvanizing; 17%, in zinc-based alloys; and 13%, in brass and bronze.

Digitized by Google

thought to be contained in the Mississippi Valley-type deposits, followed by sedimentary-exhalative deposits (31%), volcanogenic massive sulfide deposits (15%), and other deposits (14%) (U.S. Geological Survey, 1998). During the past 20 years, sedimentary-exhalative deposits have grown in importance because they usually occur in well-defined areas and are characterized by large tonnages and high grade, allowing for the development of large-capacity mines. These deposits, unfortunately, are usually fine-grained and metallurgically difficult to treat.

Production

Mine Production.—The Red Dog area in Alaska is considered the most significant zinc district in the world. Accordingly, Cominco Ltd. spent 36% of its total exploration expenditure ($33 million) in this area in 2000. Most of the drilling was carried out to delineate the Anarraaq deposit, which was discovered in 1999, 10 km northwest of Red Dog. The deposit is estimated to contain 17.2 Mt of inferred resources grading 15.8% zinc, 4.8% lead, and 71 grams per ton (g/t) silver. Together, the five deposits at Red Dog—Anarraaq, Aqqaluk, Main Zone, Paalaaq, and Qanaiyaq—have total resources of 148 Mt grading 16.6% zinc, 4.5% lead, and 85 g/t silver (Cominco Ltd., 2001).

In February 2000, Cominco Alaska Inc., subsidiary of Cominco Ltd. of Canada, began a $90 million Mill Optimization Project (MOP) designed to bring the mill at the Red Dog Mine up to its full operational potential. The project will include an upgrade of existing water treatment capacity, a new large-capacity zinc thickener, a major addition to flotation capacity and backup power generation, and enlargement of fuel storage capacity. These improvements will allow Cominco Alaska to produce 1.1 million metric tons per year (Mt/yr) of zinc concentrate, at a 87% recovery rate by the second half of 2001. Comparable figures for 2000 were 959,800 t of concentrate, containing 55.3% zinc, and average mill recovery rate of 83%. Increased production at the Red Dog Mine will partly compensate for planned closures of Cominco's Polaris and Sullivan mines in Canada (Platt's Metals Week, 2000c).

In September, Cominco approved the reopening of the Pend Oreille zinc-lead mine in Washington State, near Metaline Falls north of Spokane near the British Columbia (BC) border and about 50 km south of Cominco's Trail smelter in BC, Canada. The $70 million project should be finished by September 2002 and is expected to produce 84,000 t/yr of zinc concentrate and 13,000 t/yr of lead concentrate for at least 10 years (Cominco News, 2001). In 1995, when Cominco acquired the property from Resource Finance Corp. (RFC), it contained reserves of 5.3 Mt grading 7.3% zinc and 1.3% lead (Platt's Metals Week, 2000f). The first recorded shipment of ore from the Pend Oreille property dates back to 1906. Production was sporadic until 1930 when a 300-ton-per-day (t/d) flotation mill was built on-site. The mill was later expanded, and in 1951 the existing 2,400-t/d mill was built. The Bunker Hill Co., which had acquired the project from the mine founder, Pend Oreille Mines & Metals Inc., in 1974, closed the mine in 1977, following a labor dispute at its electrolytic plant in Idaho. Pintlar Corp., a wholly owned subsidiary of Gulf Resources & Chemical Co., acquired Pend Oreille and optioned the property to RFC in 1988. In 1996, Cominco bought RFC, including the Pend Oreille Mine (Northern Miner, 2000a). During 2000, an extensive drilling program outlined a 2-Mt resource at Washington Rock, 2 km southwest of the existing mine (Cominco Ltd., 2001).

Grupo Mexico S.A. de C.V. announced in December that it has completed the organization of a new, U.S.-based mining and minerals subsidiary, which will operate under the name of Americas Mining Group (AMG). The reorganization was triggered by the acquisition of ASARCO Inc. in November 1999. AMG includes not only Grupo's interest in Asarco, but also Southern Peru Copper Corp. and Grupo Minero Mexico. It will also include separate purchasing and sales offices. The new subsidiary will be staffed by personnel from the existing Grupo Mexico units and will be headquartered in Phoenix, AZ. After the merger with Asarco, Grupo Mexico became a diversified mining and transportation company that ranks internationally as the fifth largest zinc producer. Its zinc interest includes three zinc mines in Tennessee (Coy, Immel, and Young) (ASARCO Inc. News, 2000).

Zinc concentrate production at Doe Run Resources Corp.'s Missouri mining complex was reduced following production changes prompted by events primarily in the lead market. After closing its West Fork and Viburnum mills in May, Doe Run began shipping ore from West Fork to the Fletcher mill and put the Viburnum #29 Mine on care and maintenance and reduced production at the Viburnum #28 Mine. Because of the closure of the Viburnum mill, ore from the Casteel Mine was transported to the Buick mill. Before all these changes, Doe Run's Missouri complex produced about 52,000 t of zinc in concentrate and about 338,000 t of lead in concentrate in 1999 (CRU International Ltd., 2000c).

Exploration.—Cypress Development Corp. has completed the third phase of exploration at the Gunman zinc oxide property in northeastern Nevada. Results of drilling indicated grades of up to 20% zinc and 171 g/t silver. Since the results far exceeded the company's expectations, a fourth phase of drilling was being planned (Mining Journal, 2000f).

In January 2001, Denver-based Summo Minerals Corp. received all assays from an 18-hole drilling program completed by yearend 2000 at the Doctor Mine zinc property in Colorado. The dominant zinc mineral in the intercepts appeared to be smithsonite, and the drilling was interpreted by geologists as a zone of mineralization averaging 15 meters (m) deep, 53 m wide, and 152 m long, with a zinc content of up to 20.7% (Mining Journal, 2001).

Consumption

Since 1993, world consumption of zinc increased every year. It continued in 2000, when world consumption, at 8.8 Mt, was more than 5% higher than 1999. In comparison, the average increase between 1996 and 1998 was only about 1.6%. Slowing worldwide consumption was partially caused by a nearly 2% decline in U.S. consumption in 2000. Because of this decline, the United States was surpassed by China as the world's largest consumer of refined zinc metal. In 2000, the United States consumed 1.32 Mt of zinc, or about 15% of world consumption. Despite falling to second place in consumption, the United States still plays an important role in world zinc markets. Any weakening of U.S. economy would not only decrease consumption of zinc on the domestic market but it could

Digitized by Google

threaten the fragile economies of some Asian countries who are disproportionately dependent on exports to the United States.

According to the International Lead and Zinc Study Group, despite growing worldwide demand for zinc in 2000, production exceeded consumption by about 130,000 t, compared with a small deficit in 1999. In the Western countries, the zinc metal deficit in 2000 amounted to 815,000 t. This deficit was more than offset by imports, mainly from China, which alone exported 561,000 t of zinc metal (International Lead and Zinc Study Group, 2001a, c).

Stocks

Producers, consumers, merchants, the LME, and the U.S. Government maintain stocks of zinc metal. The surplus production of 130,000 t in 2000, had little effect on these stocks. After several consecutive years of market deficit, the draw down of LME stocks continued in 2000; by the end of December it fell to 195,000 t from 291,000 t at the beginning of 2000. The only stocks that increased in 2000 were in consumers' and merchants' warehouses. By the beginning of 2001, the overproduction of zinc metal during the previous year began to show in expanding stocks at all levels, except at the U.S. Government stockpile (International Lead and Zinc Study Group, 2001b).

Prices

Zinc concentrate production cost in the Western world's major mining countries in 2000 ranged between 29 cents per pound of contained zinc in Ireland to 39.5 cents per pound in the United States (Roskill Information Services Ltd., 2001, p. 49). In comparison with 1999, the average zinc metal cost increased by an estimated 10%, owing to higher concentrate treatment charges and reduced byproduct credits. These higher charges at smelters, plus increased fuel prices, have more than offset a continuing decline in mining and labor costs in many countries (Mining Journal, 2000h). The increase in zinc metal production cost, however, had no effect on zinc metal prices. From a level which was already hard to justify against declining stocks, zinc prices dropped further as worries over the probability of a world economic slowdown increased. In the United States, the composite price for North American Special High Grade zinc declined by nearly 9% from January to December 2000. The decline in price intensified during the past 4 months when the U.S. economy began slowing down. From September 2000, when the price reached 60.04 cents per pound, the highest for the year, it declined to 52.57 cents per pound by the end of December.

World Review

Australia.—The Australian Bureau of Agricultural and Resource Economics (ABARE) reported an 11% increase in the gross value of Australia's mine production in fiscal year (FY) 2000 (ended June 30). Increased investment in mining operations and exploration prior to FY 1998, as well as rising commodity prices and an upturn in global economic growth, contributed to an increase in production of almost all minerals. Substantial increases in production are forecast for the next fiscal year; one of the largest increases (nearly 20%) is expected to be in the production of zinc in concentrate. Increased production will be reflected in increased metals and minerals exports, which are anticipated to rise in FY 2001 by 13%. New capital investment fell by about 40% in FY 2000, and is forecast to fall a further 6% in FY 2001. There was a similar decline in exploration expenditures, which could have been the result of cost-cutting measures by producers uncertain of the long-term price outlook. According to ABARE, the medium-term outlook (for the next 5 years) for the mining industry is not promising. Export earnings are expected to be placed under downward pressure by the steady appreciation of the Australian dollar from its current historic low (U.S. Embassy, 2000).

The Premier of Queensland officially opened Pasminco Ltd.'s Century zinc mine on April 4, 10 years after the first exploration drill-holes intersected significant mineralization. The Century deposit, which is 250 km from Mount Isa in the most northern part of Queensland, now supports the world's largest zinc mine. The final development cost was $498 million, about 10% below budget. The first 10,000 t of zinc concentrate, produced from the development ore, was shipped to Pasminco's Budel smelter in the Netherlands in December 1999. By mid-April 2000, 100,000 t of high-grade concentrate was shipped to the Budel smelter. Shipments to other customers began in May. At full output, Century will produce 500,000 t/yr of zinc in concentrate (Platt's Metals Week, 2000e). The concentrate will be pumped through the 304-km-long pipeline to the Gulf of Carpentaria. From there, about one-half of the concentrate will be shipped to the Budel smelter and the rest to various smelters, mostly in Asia.

At the same time as the Century Mine is reaching full capacity, preparations are underway to close its century-old zinc mining operations at Pasminco's Broken Hill area in New South Wales. As a prelude to the impending closure in 2006, 52 jobs will be eliminated by the end of April 2000, reducing the number of miners to less than 600 for the first time since the mine opened (American Metal Market, 2000b).

Western Metals Ltd. will spend $6.7 million to expand the Pillara mining complex, in the Kimberley region of Western Australia. Western Metals' overall zinc production will likely remain the same because the increased production at Pillara will be offset by the closure of the Hallyer zinc-lead mine and pending closure of the aging concentrator at Cadjebut. The expansion of the Pillara concentrator from 1.5 Mt/yr to 2.4 Mt/yr of ore processing capacity is expected to reduce the annual cost of beneficiation by some $3.2 million. In addition, Western Metals expects ore from the deeper deposit to have a much higher grade, so that contained metal output is likely to rise substantially. Samples from greater depth showed mineralization as high as 12% zinc, compared with the current 8.4%. Production at the Pillara Mine is to rise by 20% to 1.8 Mt/yr of ore; the remaining 0.6 Mt of ore, needed for the expanded concentrator, will be trucked in from the nearby Western Metals' Kapok Mine (Metal Bulletin, 2000o).

Work on the George Fisher project in Australia continued in 2000 with upgrading of the existing lead-zinc concentrator. Capacity of Mount Isa, 22 km south of George Fisher, was expanded to 2.5 Mt/yr, and its regrinding, cleaning, and thickening processes were upgraded. During testing, recoveries reached 73.4% for zinc and 78.8% for lead. Limited production from the George Fisher Mine began at the end of 2000, 6 months ahead of schedule. At full capacity, the mine will

Digitized by Google

produce 170,000 t/yr of zinc in concentrate (Mining Journal, 2000e).

Kagara Zinc Ltd. of Australia has secured a second expansion deal for its Mount Garnet zinc project in northern Queensland. The company signed an agreement with Lachlan Resources NL to acquire 100% interest in the Balcooma project 120 km southwest of Mount Garnet and 230 km northwest of Townsville, where Korea Zinc Co. Ltd.'s new zinc smelter/refinery is located. The new acquisition included the high-grade Surveyor 1 zinc-lead deposit, which Kagara immediately incorporated into its current development plans for Mount Garnet. About 87% of the 659,000 t of resource was classified in the measured category and contained 16.7% zinc, 6.7% lead, 1% copper, 142 g/t silver, and 1 g/t gold. The deposit will initially be mined as an open pit, with the ore being trucked to nearby Mount Garnet for processing. The cash payment for Balcooma was $3 million plus a convertible loan note valued also at $3 million. If converted, Lachlan would own a 15% stake in Kagara. Kagara also negotiated an option to acquire a 100% interest in the nearby Muldiva property from a consortium that includes Barramundi Gold Ltd. and a number of prospectors. Muldiva comprises three exploration licenses covering 330 square kilometers (km^2), about 100 km north of Mount Garnet. At the beginning of the year, when Kagara bought a 75% interest in the Mount Garnet project, it also acquired a 75% interest in the nearby King Vol deposit from Perilya Ltd. (Mining Journal, 2000g). At this stage, Kagara intends to treat about 500,000 t of ore from Mount Garnet and Balcooma and produce about 40,000 t of zinc in concentrate to be trucked to the Townsville plant.

According to Sun Metals Corp., subsidiary of Korea Zinc Co. Ltd., the Townsville smelter/refinery in Australia achieved its nameplate capacity of 170,000 t by yearend 2000, despite only having opened in November 1999. Planned expansion, which would double the capacity, will depend on the availability of inexpensive power and on high price for zinc. Because the main market for Sun Metals' zinc is Southeast Asia, where the economy has not yet fully recovered, expansion is unlikely to take place for at least 5 years. Sun Metals sources its concentrates from four mines, the Century, Mount Isa, and Pillara Mines in Australia and the Red Dog Mine in Alaska (Metal Bulletin, 2000l).

Brazil.—Brazilian zinc producer, Cia Paraibuna de Metais, is planning a $100 million expansion of its Juiz de Fora smelter that would more than double zinc production over the next 3 years. The first step, which has already begun, is the debottlenecking project that will increase production from the current 77,000 t/yr to 86,000 t/yr. The major part of the expansion, to reach 170,000 t/yr of refined zinc, involves building of two new power plants of 50 and 40 megawatt capacity. A $1.77 million feasibility study is already underway. On completion of the feasibility study, the Brazilian Government will offer a tender for the construction of the two powerplants. Production at Cia Mineria de Metais' Tres Maria, the second of two Brazilian smelters, is also to increase from 120,000 t/yr to 160,000 t/yr by 2002. Although three new galvanizing plants will come on-stream in 2001, the anticipated increase of domestic consumption may not be enough to absorb the increased output of both refineries. Consequently, some of the refined zinc will probably be exported (Metal Bulletin, 2000j).

Canada.—In June 2000, Expatriate Resources Ltd. of Vancouver acquired 100% of Cominco Ltd.'s interest in some 2,800 mineral claims in the Finlayson Lake volcanogenic belt in southeast Yukon Territory, including the Kudz Ze Kayah polymetallic deposit. The purchase cost $1 million in cash and $10 million in convertible debentures is to be repaid over 4 years, with $1 million payable in each of the first 3 years and the remainder due on the fourth anniversary of the purchase (Northern Miner, 2000c). In addition to the claims, the purchase included Cominco's water license for development of Kudz Ze Kayah, the surface lease for an access road, and an agreement with indigenous local groups. The purchase allows Expatriate to combine these newly acquired deposits with its 60%-owned Wolverine deposit, to form a single exploration and development project. Expatriate has solved the processing problems associated with the high selenium content of its Wolverine deposit simply by comilling the ore with that of the nearby Kudz Ze Kayah deposit. The two deposits contain an overall resource of 19.2 Mt grading 8% zinc, 1.6% lead, and 1.05% copper, plus gold and silver. Average annual production is anticipated to be about 87,000 t of contained zinc, 13,000 t of lead, and 10,500 t of copper, as well as 1,200 kilograms (kg) of gold and 180 t of silver over the life of the project. The prefeasibility study calls for the upper part of the Kudz Ze Kayah deposit to be mined by an open pit method at the rate of 3,000 t/d. The Wolverine deposit will be developed as a 1,250-t/d underground mine, with the ore trucked 35 km to a processing facility at Kudz Ze Kayah. The concentrate will be trucked 700 km to Skagway, AK, for shipment to smelters in Asia and eastern Canada (Northern Miner, 2000d).

Noranda Inc. of Canada suspended operations at its newly opened Bell-Allard zinc underground mine and mill for a period between February 24 and April 6. The mine, near Matagami, Quebec, was closed because a hoisting skip malfunctioned and damaged the mine's underground shaft compartment. No one was injured in the incident. Operation of Noranda's refinery at Valleyfield was not affected, because sufficient stocks of concentrate existed at the plant. The mine began operation at the start of 2000, reaching 65% of its 2,000 t/d capacity before the accident (Mining Journal, 2000b).

Noranda uncovered a zinc-rich massive sulfide zone during initial exploration in Perseverance, Quebec, near its Bell-Allard zinc mine. Samples from the site's 10 drill holes contained between 13.5% and 25.5% zinc, in addition to 11.8 g/t to 47.1 g/t silver and traces of copper. The Perseverance project is a joint venture between Toronto-based Noranda, which holds a 90% interest, and Societe de Development de la Baie James (SDBJ), which has an option to acquire 10% interest in the mine after completing a positive feasibility study. SDBJ has the option of converting its 10% interest in the mine to a 2% net smelter royalty, leaving Noranda with 100% interest in the mining operations (American Metal Market, 2000a).

Cambior Inc. continued its downsizing by completing the sale of its Bouchard-Hebert and Langlois zinc mines in the Abitibi region of northwestern Quebec to Breakwater Resources Ltd. for $48 million. The transaction, which took place in April 2000, effectively took Cambior out of the zinc business. At the same time, the acquisition gave Breakwater an additional output of copper, gold, and zinc. In addition to copper, Bouchard-Hebert produced a total of 39,100 t of zinc in 1999 and had reserves of 5.3 Mt grading 4.73% zinc. During the same year,

Digitized by Google

Langlois produced 31,700 t of zinc in concentrate and had reserves of 5.6 Mt grading 9.45% zinc (Platt's Metals Week, 2000b). Together with other Breakwater mines, the company hoped to produce about 226,000 t of zinc concentrate in 2000 and 258,000 t in 2001 (Metal Bulletin, 2000b). However, by early December, Breakwater suspended operations at its Langlois zinc mine, owing to problems with the main ore transportation system. Together with low metal prices and high treatment charges, the problems made the operation of the mine uneconomic. Immediately after closing the mine, Breakwater begun developing a plan to optimize the life of the mine. The new plan should be completed early in 2001, and the company may begin production by the first quarter of 2002 (Metal Bulletin, 2000c). Since 1995, Breakwater's zinc production expanded more than six-fold, making it the world's eighth largest producer of zinc.

Falconbridge Ltd. of Canada approved deepening of the Kidd Creek Mine at Timmins, Ontario. The mine will be extended by 1,000 m to 3,100 m below the surface at a cost of $430 million. During the first stage, the mine will be extended to 2,700 m. It will involve sinking of a new shaft, installation of a new ventilation, a refrigeration system, and purchase of new underground equipment. Stage one, which should be completed by 2004, would give Falconbridge access to a part of the mine that contains 16 Mt of ore grading 5.74% zinc, 2.82% copper, and 58 g/t silver. Stage two is to begin in 2010. The reserve estimate for that part was 11 Mt of ore grading 5.3% zinc, 2.2% copper, and 100 g/t silver (Mining Engineering, 2000).

Major zinc producer, Billiton Metals Canada Inc., subsidiary of London-based Billiton plc, first agreed but later withdrew from participation in the development of the Howards Pass zinc project (owned by Copper Ridge Explorations Inc.), which straddles the border between the Yukon Territory and the Northwest Territories in Canada. The major attraction of the Howards Pass property is that it is believed to be one of the largest undeveloped zinc deposits in the world, with resources estimated at 110 Mt grading 7.7% zinc, plus lead, cadmium, and silver. Lack of infrastructure and metallurgy pose challenges for development (Metal Bulletin, 2000a). Original prefeasibility evaluation indicated that Howards Pass could not be mined economically, owing to the above mentioned lack of infrastructure and the high cost of traditional milling and smelting. Like many shale-hosted exhalative deposits, Howards Pass has a fine-grained mineralization that requires long grinding times and large mills. In addition, the mineralization is graphite-rich, which harms recoveries in conventional flotation. Copper Ridge hopes to overcome these difficulties by producing bulk zinc, lead, cadmium, and silver concentrate in a mill circuit, comprising gyratory crushing, semiautogenous grinding, and flotation. Concentrates would be transported south by a slurry pipeline to a pressure leaching, purification, and electrowinning plant at the Robert Campbell Highway, near Frances Lake, or possibly Watson Lake. Annual production is estimated at 350,000 t to 500,000 t of zinc metal, depending on the grade of ore mined (Northern Miner, 2000b).

China.—London-based Billiton plc, formed an "Incorporated Contractual Joint Venture" (ICJV) with Chinese Lanping Nonferrous Metals Co. (LNMC) to develop the Lanping zinc deposit in China. Billiton, through its wholly owned Billiton China BV, eventually will hold 65% of the ICJV. LNMC, is 51%-owned by Yunnan Metallurgy Group, which is wholly owned by the provincial government. Thus, the agreement represented the first commercial joint venture between the Chinese provincial government and an international mining company in which a foreign company has taken a majority stake in a mineral project in China. The Lanping deposit is in Yunnan Province, western China, near the border with Burma. It is described as one of the world's largest undeveloped zinc mineralization, measuring 200 Mt at a grade in excess of 10% zinc. A feasibility study should be completed at the end of 2001. The project could involve a capital investment of about $500 million. When developed, the Lanping facility is expected to produce between 250,000 t and 270,000 t of zinc metal per year (Mining Journal, 2000d).

Congo.—Zinc Corp. of South Africa (Zincor) restated its interest to exercise its option to join America Mineral Fields International Inc. (AMFI) in redevelopment of the historic Kipushi Mine in Congo (Kinshasa). Zincor can earn up to a 50% interest in the proposed joint venture by matching AMFI's expenditures on the project. The joint venture will include a formal agreement with La Générale des Carrières et des Mines, the Congolese mining corporation that owns the Kipushi Mine. The agreement will cover equity ownership, project finance, and dividend distribution. Pending the outcome of a feasibility study and approval by the board of directors, the project could commence once the Congolese Government grants approval. The Kipushi Mine operated from 1925 until 1993, when it was placed on care and maintenance. The mine has measured and indicated resources of 17 Mt grading 16.7% zinc and 2.32% copper. Zincor is a wholly owned subsidiary of Iscor Ltd., the South African iron, steel, and mining group (American Metal Market, 2000d). With minimal initial expenditure, the Kipushi Mine could produce as much as 30,000 t/yr of contained zinc in concentrate, beginning in the first half of 2001. Concentrate would be transported by rail for processing at Zincor's 115,000 t/yr zinc refinery at Springs, South Africa, near Johannesburg (Platt's Metals Week, 2000h).

Ireland.—In 2000, Tara Mines Ltd., subsidiary of Finnish base metal producer Outokumpu Oy, had to resolve two strikes at its Tara Mine at Navan, northwest of Dublin. After a 7-month-long labor dispute, the first strike ended in February, with a Government brokered deal that included an agreement on miners' bonuses and pay, extended shift schedules with increased shift premium payments, and the use of contract workers. Because of the vagueness of the agreement concerning contract workers, a new 2-week strike erupted in November. The new agreement provided for a new training program for 60 workers at the mine and allowed for the interim use of contract workers until the end of August 2001 (Platt's Metals Week, 2000i). Following the successful resolution of the first strike, Outokumpu Oy of Finland approved a mine-life extension of its Tara Mine. At the annual production level of 200,000 t of concentrate, the $43 million extension will add at least 8 years to Tara's mine life. Production from the new southwest extension, measuring 10 Mt and averaging 9% zinc and 2% lead, should start in 2001, and it is anticipated that full capacity will be achieved by 2004 (Mining Journal, 2000i).

The Galmoy zinc-lead mine in County Kilkenny, owned by Arcon International Resources plc, has begun using a three-stage flotation process that reduced by 75% the amount of material that had to be put back through the regrind circuit. Arcon also has doubled the capacity of its acid leach process,

Digitized by Google

reducing the magnesium content of the concentrate to 0.44% MgO and improved recoveries to about 87%. The original reserve had been increased through exploration from 6 Mt to 8 Mt grading 11.5% zinc and 1% lead (Metal Bulletin, 2000e).

By the second half of 2000, the Lisheen zinc-lead mine reached full production capacity of 330,000 t/yr of zinc and 40,000 t/yr of lead in concentrate. The mine, 160 km southwest of Dublin in County Tipperary, is jointly owned by Ivernia West plc and Minorco SA (Platt's Metals Week, 2000d). The Lisheen Mine is the third largest zinc mine in Ireland, following Tara and Galmoy. By yearend 2000, these mines reached a combined annual production of about 700,000 t of zinc concentrate, making Ireland one of the world's major zinc producers. Lisheen's proven reserves of 18.9 Mt grading 12.8% zinc and 2.2% lead are in 3- to 7-m-thick seams in two adjacent ore bodies: Main and Derryville. Concentrates, which are described as low in iron with normal levels of cadmium, cobalt, and nickel, are trucked 110 km to Cork where sheds and shiploading facilities have been leased (Metal Bulletin Monthly, 2000).

Kazakhstan.—According to CRU International Ltd. (2000a), the zinc industry of Kazakhstan continues to expand. The expansion of Kaztsink's Maleevsk Mine was completed in July at a cost of $65 million. Increased production at the Maleevsk Mine has offset the closure of the Zyryanovsk Mine. Reserves at Maleevsk are estimated at 36.7 Mt grading 7.7% zinc, 2.6% copper, 1.2% lead, and some gold and silver. An additional contribution will come from the Tishin Mine, where an investment of $6 million should raise production to 1.4 Mt of ore in 2001 (CRU International Ltd., 2000b). Kaztsink's self-sufficiency increased to 71% in 2000 from 54% in 1999; complete self-sufficiency should be achieved by 2001. Slab zinc production in 2000 increased to 262,570 t. At Leninogorsk, which produced about 40% of the company's slab zinc in 2000, Kaztsink proposed to expand capacity by 20% through various new investments. It also planned to increase output at its Ust-Kemenogorsk smelter from 144,200 t/yr in 2000 to 156,000 t/yr in 2001 (CRU International Ltd., 2001).

The biggest contribution to the expanding zinc industry is to come from the Shaimerden oxide-silicate deposit in the Kustanai region of Kazakhstan. The Irish company, Ennex International Ltd., through its subsidiary Zinc Corp of Kazakhstan owns 95% of the project and already concluded a feasibility study. The operation, which will be technically similar to that of Skorpion in Namibia, is to produce 100,000 t/yr of zinc metal over a 6 to 10 year period. Resources are 4.3 Mt grading 21% zinc. The cost of development is estimated to be about $250 million and should result in an exceptionally low operating cost of about 21 cents per pound (Roskill, 2001, p. 115).

Mexico.—During 2000, Industrias Peñoles S.A. de C.V. twice increased the capacity of its Torreón metallurgical complex: early in the year it went from 130,000 t/yr to 160,000 t/yr, and in December it increased to 220,000 t/yr because of increased domestic demand, mainly for zinc alloys due to growth in the construction and automobile sectors (Metal Bulletin, 2000m). Additional zinc concentrate for this expanding production came from increased output at existing mines and, later, two new mines: the Rey de Plata and the Francisco I. Madero. In early October, Mexico's Industrias Peñoles S.A. de C.V. opened its new zinc mine in the coastal state of Guerrero, potentially raising its annual zinc production by 12%. The Rey de Plata Mine is expected to produce 20,000 t/yr of zinc in concentrate by 2001, making it the fifth largest zinc mine in Mexico. The mine is owned 51% by Peñoles, 39% by Dowa Mining Co. Ltd. of Japan, and 10% by Sumitomo Corp., a major Japanese trading company. The Rey de Plata Mine, in Tehuixtla, will create 465 new jobs directly and about 1,000 indirect employment opportunities (American Metal Market, 2000c). The Francisco I. Madero Mine is to produce 96,000 t/yr of zinc concentrate by 2001 (Platt's Metals Week, 2000g).

Namibia.—Anglo American plc is to spend $454 million developing the Skorpion zinc mine and refinery in southern Namibia. The Skorpion Mine is expected to produce about 150,000 t/yr of zinc in concentrate by 2003 over a mine life of at least 15 years. The Skorpion deposit contains reserves of 21.4 Mt grading 10.6% zinc, minable by conventional open pit method. The ore is unusual in that it consists mainly of zinc silicates and zinc carbonates, rather than the more typical zinc sulfide (sphalerite). Accordingly, a special metallurgical process has been developed, consisting of a direct acid leaching of the ore, solid-liquid separation, solvent extraction, and electrowinning to produce special high-grade zinc. When at full capacity, the cost of production should be around $0.20 and $0.23 per pound, making Skorpion one of the lowest cost producers in the world (Miningweb, September 7, 2000, Anglo gives green light to $454 million zinc venture, accessed September 7, 2000, at URL http://www.mips1.net/422567CB004ED3BF/(UNID)/DMKY-4NXM9G).

Peru.—Rio Algom of Canada, Ltd. agreed to a friendly takeover by Billiton plc on August 25. The main incentive for the purchase lies in Rio Algom's 33.75% share in the Antamina copper-zinc project in Peru. The project is already 52% complete and engineering work is 95% finished. Annual production in the first 10 years is expected to be 270,000 t of copper and 160,000 t of zinc (Mining Journal, 2000c). The massive Antamina copper-zinc deposit in Peru is larger than previously believed. Based on new drill results, combined proven and probable reserves increased in volume by 13%, in addition to slightly higher zinc and silver grades. Proven reserves now stand at 313 Mt grading 1.3% copper, 1.06% zinc, 0.03% molybdenum, and 14.13 g/t silver. Probable reserves amount to 246 Mt grading 1.15% copper, 0.99% zinc, 0.028% molybdenum, and 13.71 g/t silver. Antamina is operated by Compañía Minera Antamina, which is now owned by Noranda Inc. (33.75%), Billiton plc (33.75%), Teck Corp. (22.5%), and Mitsubishi Corp. (10%). The project is slated to become the world's third largest zinc producer. Construction is on schedule for full production to begin in late 2001 (Northern Miner, 2000e).

Compañía Minera Volcán S.A., presently Peru's largest privately owned zinc producer, added about 30,000 t of high-grade zinc concentrate to its current production by purchasing the neighboring Chungar and Vinchos Mines for $24 million. The purchase also included the supply of hydroelectric generating capacity, 382 hectare (ha) of land from the majority owners of the Chungar Mine, and 5,700 ha of exploration property from the owners of the Vinchos Mine. The latter property is near Volcán's Paragsha Mine. Over the past 3 years, Volcán has risen from relative obscurity to the largest zinc producer in Peru by purchasing the Mahr Tunel Mine from the

Digitized by Google

Government and later buying the Paragsha (formerly Cerro de Pasco) Mine from Centromin (Empresa Minera del Centro del Peru S.A.) (Metal Bulletin, 2000n). Volcán is also planning a $70 million investment over the next 5 years to increase production at its recently purchased Paragsha Mine (Metal Bulletin, 2000k).

Portugal.—Canadian zinc producer EuroZinc Mining Corp. received the final feasibility study for the Aljustrel polymetallic project in southern Portugal in June 2000. The study called for an underground operation producing about 1.6 Mt of ore, with potential for an increase to 2 Mt. The mine was expected to produce 65,800 t of zinc 15,400 t of lead, and 34 t/yr of silver during the first 9 years and 13,600 t/yr of copper in the following 2 years. Aljustrel was estimated to contain proven and probable reserves of 13.8 Mt grading 5.3% zinc, 1.77% lead, 0.26% copper, and 63 g/t silver. EuroZinc received a $32 million incentive package from the Portugese Government towards the $75 million that will be required for the development of the mine. A smaller part of the financing will be used for restarting the production at the Moinho Mine where underground infrastructure is in excellent condition. The proceeds from Moinho production will be used to supplement financing for the Feitais deposit, development of which will take about 2 years. The mine was closed in mid-1999 because of low zinc prices and inefficient mining and milling methods. Recent discoveries and modifications to the milling process should enable profitable mining when the mine is scheduled to reopen in 2001. EuroZinc will earn up to 75% interest from the Government-owned Empresa de Desenvolvimento de Miniero mining company by advancing the project to the production stage (Mining Journal, 2000a).

South Africa.—In September 2000, the board of directors of Anglo American plc approved the development of its Skorpion (Namibia) and Gamsberg (South Africa) zinc projects. The Gamsberg project is expected to produce 300,000 t/yr of refined zinc from 6 Mt/yr of ore containing 6% zinc (Platt's Metals Week, 2000a). Construction may begin in January 2001 and is expected to be completed within 3 years. The Gamsberg Mine project, near Aggeneys in the Northern Cape, will contain an open pit mine 4.5 km^2 and 540 m deep. The mining site will also include a concentrator, two waste rock dumps, and one tailings dam (Metal Bulletin, 2000f).

Spain.—The future of Boliden Ltd.'s Los Frailes zinc mine is in doubt after the Canadian company has decided not to develop pit #3, although it will proceed with developing pit #2. The development of pit #3 would involve stripping back overburden at an additional cost of $26 million, before any revenues are generated from pit #2. Because Boliden does not have the financial resources nor the ability to borrow the necessary funds, its Spanish subsidiary, Boliden Apirsa S.L., has filed a Spanish equivalent of Chapter 11 bankruptcy protection. It would allow Apirsa to preserve assets, pay creditors, and ensure that operations at Los Frailes will continue until the completion of pit #2, planned for October 2001. Apirsa has been incurring significant financial losses since resumption of operations in 1999 after a rupture in the mine's tailings dam (Metal Bulletin, 2000d).

Navan Mining plc (formerly Navan Resources plc) of the United Kingdom has more than doubled its zinc production at its new Aguas Teñidas Mine. By the end of 2000, production rate reached 600,000 t/yr of zinc ore grading 8.7%. During the year, existence of a westward extension of resource was discovered, increasing the overall resource by 10% to 15%, and probably extending the life of the mine beyond the anticipated 15 years. Crushed ore is transported 28 km by road to the Almagrera processing plant (Metal Bulletin, 2000g).

Thailand.—Union Minière SA of Belgium has purchased a 33% interest in Thai zinc producer Padaeng Industry Co. Ltd. The infusion of investment helped Tak smelter, Thailand's sole zinc smelter, to expand production to 101,000 t/yr in 2000 from 95,400 t/yr in 1999. Nearly three-fourths of production was sold on the domestic market; the remaining one-quarter was exported. Domestic consumption of zinc is expected to grow by 5.6% in 2001 and by about 30% in the next few years (Metal Bulletin, 2000h).

In mid-2000, Padaeng signed an agreement on zinc mining and processing with the Government of Laos, covering a 12 km^2 area near Kaiso, north of Vientiane, Laos. Ore from the planned mine will be blended with silicate ore from Padaeng's Mae Sod Mine in Thailand, to produce an even higher quality concentrate for its 106,000-t Tak smelter (Metal Bulletin, 2000i).

Outlook

According to the CEO of Cominco, the zinc industry is ripe for a wave of consolidation comparable to aluminum and copper industries during the past 2 years. The main benefit of mergers would be the ability of a small number of producers to manage resources and capital more effectively, avoiding wasteful investment in unprofitable projects. Even this consolidation may not be enough to improve the low profitability of the zinc industry, which earned a 0.7% return on equity between 1990 and 1999, compared with a 10.3% return for copper producers. Zinc metal prices have been falling 2.3% in real terms for the past 30 years (Platts Metals Week, 2001). Zinc prices most likely will continue to decline in 2001 because zinc production is forecast to increase by 4.6% to 9.34 Mt, while consumption is expected to increase by only 0.2% to 8.83 Mt (Metal Bulletin, 2001).

In contrast to other base metals, there is virtually no mine-site smelting of zinc concentrates, and the volume of zinc concentrates moving either within or across borders is large. Asia and Europe accounted for 72% of world zinc metal production and only 41% of mine production in 2000. America and Australia, on the other hand, accounted for 56% of world mine production and only 26% of metal production in 2000. Although there was significant integration of zinc mining and smelting within a few large companies in the past, it did not increase in the late 20th century. This pattern could begin to change with construction of Skorpion and Shaimerden mining and refining complexes in Namibia and Kazakhstan, respectively.

TABLE 1
SALIENT ZINC STATISTICS 1/

(Metric tons, unless otherwise specified)

		1996	1997	1998	1999	2000
United States:						
Production:						
Domestic ores, contained zinc		628,000	632,000	755,000	813,000 r/	829,000
Domestic ores, recoverable zinc		586,000	592,000	709,000	771,000 r/	786,000
Value, recoverable zinc	thousands	$660,000 r/	$843,000 r/	$804,000 r/	$909,000 r/	$1,020,000
Refined zinc:						
From domestic ores		214,000	195,000	192,000	180,000	137,000
From foreign ores		11,400	31,700	41,900	61,100	90,900
From scrap		140,000	140,000	134,000	131,000	143,000
Total		366,000	367,000 r/	368,000	371,000	371,000
Secondary zinc 2/		238,000	234,000	292,000	267,000	290,000
Exports:						
Ores and concentrates (zinc ocntent)		425,000	461,000	552,000	531,000	523,000
Slab zinc		1,970	3,630	2,330	1,880	2,770
Rolled zinc		5,020	9,110	9,920	3,870	3,530
Imports for consumption:						
Ores and concentrates (zinc ocntent)		15,100	49,600	46,300	74,600	52,800
Refined (slab) zinc		827,000	876,000	879,000	966,000	915,000
Rolled zinc		16,900	19,200	16,900	22,600	9,380
Stocks of slab zinc, December 31:						
Producer		11,100	9,360	9,060	9,960	7,890
Consumer		59,700	60,400	45,400	64,400	58,300
Merchant		4,800	18,500	13,300	9,690	10,500
Total		75,600	88,200	67,700	84,100	76,600
Government stockpile		258,000 r/	225,000	199,000	177,000	138,000
Consumption:						
Refined zinc:						
Reported		788,000	672,000	647,000	614,000	640,000
Apparent 3/		1,210,000	1,260,000	1,290,000	1,340,000	1,330,000
All classes 4/		1,450,000	1,490,000	1,580,000	1,610,000	1,620,000
Price, special high grade	cents per pound	51.11	64.56	51.43	53.48	55.61
World:						
Production:						
Mine	thousand metric tons	7,480	7,530 r/	7,690 r/	8,040	8,730 e/
Smelter	do.	7,610 r/	7,920 r/	8,160 r/	8,570 r/	9,050 e/
Price, London Metal Exchange	cents per pound	46.50	59.70	46.45	48.80	51.15

e/ Estimated. r/ Revised.

1/ Data are rounded to no more than three significant digits, except prices; may not add to totals shown.

2/ Zinc in metal products and compounds derived directly from scrap; refined secondary zinc is listed separately in the table.

3/ Domestic production plus net imports, plus or minus stock changes.

4/ Apparent consumption of refined zinc plus reported consumption of zinc in metal products and compounds derived directly from ore, concentrate, or scrap.

TABLE 2
MINE PRODUCTION OF RECOVERABLE ZINC IN THE UNITED STATES, BY STATE 1/

(Metric tons)

State	1999	2000
Alaska 2/	563,000	574,000
Missouri	48,700	51,800
Montana	22,200	16,600
Other 3/	137,000 r/	143,000
Total	771,000 r/	786,000

r/ Revised.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Data based, in part, on publicly available information.

3/ Includes production from Idaho, New York, and Tennessee.

TABLE 3
LEADING ZINC PRODUCING MINES IN THE UNITED STATES IN 2000, IN ORDER OF OUTPUT

Rank	Mine	County and State	Operator	Source of zinc
1	Red Dog	Northwest Arctic, AK	Cominco Alaska Inc.	Lead-zinc ore.
2	Greens Creek 1/	Juneau, AK	Kennecott Greens Creek Mining Co.	Zinc ore.
3	Balmat	St. Lawrence, NY	Zinc Corp. of America	Do.
4	Gordonsville	Smith, TN	Pasminco Ltd.	Do.
5	Young	Jefferson, TN	ASARCO Inc.	Do.
6	Montana Tunnels	Jefferson, MT	Apollo Gold Co.	Do.
7	Brushy Creek	Reynolds, MO	Doe Run Resources Corp.	Lead ore.
8	Pierrepont	St. Lawrence, NY	Zinc Corp. of America	Zinc ore.
9	Immel	Knox, TN	ASARCO Inc.	Do.
10	Buick	Iron, MO	Doe Run Resources Corp.	Lead ore.
11	West Fork	Reynolds, MO	do.	Do.
12	Casteel	Iron, MO	do.	Do.
13	Cumberland	Smith, TN	Pasminco Ltd.	Zinc ore.
14	Coy	Jefferson, TN	ASARCO Inc.	Do.
15	Fletcher	Reynolds, MO	Doe Run Resources Corp.	Lead ore.
16	Clinch Valley	Grainger, TN	Pasminco Ltd.	Zinc ore.

1/ Updated to reflect locality name change.

TABLE 4
REFINED ZINC PRODUCED IN THE UNITED STATES 1/

(Metric tons)

	1999	2000
Primary:		
From domestic ores	180,000	137,000
From foreign ores	61,100	90,900
Total	241,000	228,000
Secondary	131,000	143,000
Grand total (excludes zinc recovered by remelting)	371,000	371,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

TABLE 5
REFINED ZINC PRODUCED IN THE UNITED STATES, BY GRADE 1/

(Metric tons)

Grade	1999	2000
Special High	93,400	82,200
Continuous Galvanizing	103,000	93,200
Other 2/	175,000	195,000
Total	371,000	371,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes Controlled Lead, High, and Prime Western grades.

TABLE 6
SLAB ZINC CAPACITY OF PRIMARY ZINC PLANTS IN THE UNITED STATES, BY TYPE OF PLANT AND COMPANY

(Metric tons)

Type of plant and company	1999	2000
Electrolytic:		
Big River Zinc Corp., Sauget, IL	95,000	100,000
Pasminco Ltd. Clarksville, TN	115,000	115,000
Electrothermic:		
Zinc Corporation of America, Monaca, PA 1/	155,000	155,000
Total	365,000	370,000

1/ Includes secondary capacity.

ZIRCONIUM AND HAFNIUM

By James B. Hedrick

Domestic survey data and tables were prepared by Mahbood Mahdavi, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

Zirconium is produced from two ore minerals. The principal economic source of zirconium is the zirconium silicate mineral zircon ($ZrSiO_4$). The mineral baddeleyite, a natural form of zirconium oxide or zirconia (ZrO_2), is a distant second to zircon in its economic significance. Zircon is the primary source of all hafnium. Zirconium and hafnium are contained in zircon at a ratio of about 50 to 1. Zircon is a coproduct or byproduct of the mining and processing of heavy-mineral sands for the titanium minerals ilmenite and rutile or tin minerals. The major end uses of the mineral zircon are refractories, foundry sands (including investment casting), and ceramic opacification. Zircon is also marketed as a natural gemstone, and its oxide is processed to produce cubic zirconia, a diamond and colored gemstone simulant. Zirconium metal is used in nuclear fuel cladding, chemical piping in corrosive environments, heat exchangers, and various specialty alloys.

The principal uses of hafnium are in nuclear control rods, nickel-based superalloys, nozzles for plasma arc metal cutting, and high-temperature ceramics.

World production of zirconium mineral concentrates was estimated to have increased slightly in 2000. Data on U.S. production and consumption of zircon concentrates were withheld to avoid disclosing company proprietary data. Domestic production of zircon increased as a heavy-mineral sand mining operation in Virginia continued to improve recovery rates and scale-up production. In 2000, production of milled zircon was essentially unchanged from that of previous years. According to U.S. Census Bureau trade statistics, the United States was a net exporter of zirconium ore and concentrates. U.S. imports of zirconium ore and concentrates increased by 13%, and domestic exports of zirconium ore and concentrates increased by 5% compared with 1999.

With the exception of prices and referenced data, all survey data in this report have been rounded to no more than three significant digits. Totals and percentages were calculated from unrounded numbers.

Production

Data for zirconium and hafnium materials are developed by the U.S. Geological Survey from one voluntary survey of domestic operations. Of the 47 operations surveyed, 25 responded, and 2 were removed because they no longer used the material. Data for zircon concentrates are developed by a second voluntary survey of domestic operations. The two domestic zircon producers, which have three mining and processing operations, responded. Data for nonrespondents were estimated based on prior year levels. Data on domestic production and consumption of zircon concentrates were withheld to avoid disclosing company proprietary data.

Domestic production of milled zircon increased slightly and production of zirconium oxide increased by 34% from their

Zirconium and Hafnium in the 20th Century

Just before the turn of the century, zirconium oxide changed the world forever from nights dimly illuminated by candles and oil and gas lamps to the bright glow of incandescent lighting. The incandescent lamp mantle industry was established in 1884 with mantles of zirconium, lanthanum and yttrium oxides. By 1900, the zirconium oxide mantle mixture had been replaced with an improved, brighter oxide mixture of thorium and cerium. That same year, the Nernst lamp, which used rods ("glowers") made of 25% yttrium oxide and 75% zirconium oxide, came into use. In this lamp, it was necessary to heat the glowers with an auxiliary device to about 700° C, at which point it became conductive, and the resistance caused it to glow with a brilliant white incandescence. With the advent of the electric incandescent lamp around 1912, zirconia's use in Nernst glowers declined. Other commercial applications of zirconium oxide in 1900 were in opacification of enamels and enamelware, in paints, and in making x-ray images. The principal use of the zirconium minerals zircon and baddeleyite was in refractory materials. Domestic zircon production at the start of the 20th century was from mines centered around Zirconia, Henderson County, NC. All production was used in the United States.

In 1900, metallic zirconium had no commercial applications, although several uses had been tried or suggested. Ferrozirconium was developed prior to World War I and used as armor plate, bullet-proof metal, and armor-piercing projectiles. In 1930, the pure metal was first used commercially in the United States as a smokeless flashlight (flash powder) in photography, a use patented in Germany 9 years earlier. This use quickly waned with the development of the flash bulb which used only a thin coating of zirconium to ignite lower cost aluminum foil.

In 2000, the United States was a major producer of zircon and zirconium. Zircon was produced at mines in Florida and Virginia and was exported to many countries, the principal destinations being Italy and Mexico, where most of it was used in the opacification of ceramic tile and sanitaryware. To meet demand, zircon was imported from several countries, the principal producing sources being Australia and South Africa. Zirconium metal and alloys were produced in Oregon and Utah. Zirconium's principal uses in 2000 were in nuclear reactor fuel cladding, heat exchangers, and corrosion resistant piping for chemical plants. Zirconium exports were shipped primarily to Canada, Japan, and the United Kingdom. The main sources of U.S. imports of zirconium were France, Germany, Japan, and Canada.

Digitized by Google

1999 levels (table 1).

Zircon is normally produced as a byproduct of the mining and processing of heavy-mineral sands containing the titanium minerals ilmenite and rutile. In 2000, U.S. mine producers of zircon were E.I. du Pont de Nemours and Co. (DuPont) and Iluka Resources, Inc. [previously RGC (USA) Mineral Sands, Inc.], a subsidiary of the Australian company Iluka Resources Ltd. DuPont produced zircon from its Highland and Maxville heavy-mineral sands deposits near Starke, FL. Iluka produced zircon from its heavy-mineral sand operations at Green Cove Springs, FL, and Stony Creek, VA. U.S. producers of zirconium and hafnium metal were Wah Chang, an Allegheny Technologies company (prior to January 2000 named Oremet-Wah Chang, a subsidiary of Allegheny-Teledyne Corp.), Albany, OR; and Western Zirconium, a subsidiary of Westinghouse Electric Co., Ogden, UT. Primary zirconium chemicals were produced by Wah Chang and Magnesium Elektron Inc., Flemington, NJ. Secondary zirconium chemicals were produced by about 10 companies, and zirconia was produced from zircon sand at plants in Alabama, New Hampshire, New York, Ohio, and Oregon.

Iluka continued to improve production output from that of the previous year at its Old Hickory Mine in Stony Creek, VA. The original zircon production capacity at Stony Creek was 30,000 metric tons per year (t/yr). Phase one of a $100 million expansion announced in 1999 by Iluka Resources Ltd. will be at the Old Hickory Mine in Virginia, and phase two, at the Green Cove Springs Mine in Florida (Mineral Sands Report, 2000d). The feasibility study for phase one was completed in 2000.

Altair International Inc. announced that it had broken ground on the construction of a pilot plant at its two heavy-mineral sand deposits near Camden, TN. The deposits contain an estimated 490 million tons (Mt) grading 3.6% heavy minerals. The prime contractor for the site clearing and settling pond construction was Hubbs contractors of Camden. MD Mineral Technologies, which had been previously selected to design and engineer the plant, is expected to oversee the plant construction and startup (Altair International Inc., June 22, 2000, Altair announces groundbreaking at Camden, accessed March 13, 2001, at URL http://www.altairint.com/News/2000/2000.html).

Consumption

Approximately 95% of all zirconium consumed is in the form of zircon, zirconium oxide, or other zirconium chemicals. The remainder is consumed as zirconium metal and zirconium-containing alloys.

Zircon, used for facings on foundry molds, increases resistance to metal penetration and gives a uniform finish to castings. Milled or ground zircon is used in refractory paints for coating the surfaces of molds. Zircon in the form of refractory bricks and blocks is used in furnaces and hearths for containing molten metals. Glass tank furnaces use fused cast and bonded alumina-zirconia-silica-base refractories. Baddeleyite is used principally in the manufacture of alumina-zirconia abrasive and in ceramic colors and refractories.

Stabilized zirconium oxide exhibits high light reflectivity and good thermal stability and is primarily used as an opacifier and pigment in glazes and colors for pottery and other ceramic products. Yttria stabilized zirconia (YSZ) is used in the manufacture of oxygen sensors that control combustion in furnaces and automobile engines. YSZ is also used in the manufacture of a diverse array of products including high temperature, high strength structural ceramics, heat- and break-resistant shirt buttons, golf shoe cleats, golf putters, fiber optic connector components, coatings for the hot sections of jet engines, and cubic zirconia, a gemstone simulant for diamonds and colored gemstones.

Because of its low thermal neutron absorption cross section, hafnium-free zirconium is used as cladding for nuclear fuel rods. Commercial grade zirconium, unlike nuclear grade, contains hafnium and is used in the chemical process industries because of its excellent corrosion resistance.

Hafnium is used in nuclear control rods because of its high thermal neutron absorption cross section. However, the largest end use for hafnium metal is as an alloy addition in superalloys.

Prices

In 2000, the increased demand for zircon concentrates resulted in an increase in price. The average value of imported ore and concentrates increased by 27% to $396 per ton in 2000 from $311 per ton in 1999. Domestic prices of standard- and premium-grade zircon increased as a result of a tightening of supply, especially for premium grades. Published prices for imported grades of zircon were higher than those of 1999. Published prices for zirconium, hafnium, and zirconium oxide products were unchanged or slightly higher (table 2).

Foreign Trade

According to U.S. Census Bureau trade statistics, the United States was a net exporter of zirconium ore and concentrates in 2000. U.S. exports of zirconium ore and concentrates were 72,900 metric tons (t), a 5% increase from that of 1999 (table 3). The United States was a net exporter of zirconium and hafnium metal in 2000. U.S. exports of unwrought zirconium metal, waste, and scrap were 180 t, a 15% increase in tonnage compared with those of 1999. U.S. exports classified as "other zirconium metal, waste, and scrap" were 1,030 t, a 22% increase from the 1999 level.

U.S. imports of zirconium ore and concentrates were 65,200 t, an increase of 7,560 t from those of 1999 (table 4). Australia and South Africa supplied about 94% of the imports of ores and concentrates. Imports of unwrought zirconium metal and waste and scrap amounted to 1,040 t, a 22% increase compared with those of 1999. The leading import sources of unwrought zirconium were, in descending order of quantity, France, Germany, and Japan. Domestic imports of ferrozirconium alloys were 281 t in 2000, a 182% increase from the previous year. Imports originated primarily from Brazil, with a minor quantity from Germany. U.S. imports of unwrought hafnium metal and waste and scrap were 11.1 t, an 18% increase compared with those of 1999.

World Review

Excluding U.S. production, world production of zirconium mineral concentrates in 2000 is estimated to be 760,000 t, a minor increase compared with that of 1999 (table 5). Australia and South Africa supplied about 82% of all production outside the United States. World reserves of zircon are estimated to be 36 Mt of ZrO_2, while identified world resources of zircon were 65 Mt of ZrO_2. During 2000, the zirconium industry continued

Digitized by Google

to be active in the exploration and development of mineral deposits on a global basis, particularly in Australia, Kenya, Mozambique, South Africa, and the United States. Iluka Resouces was the world's largest producer of zircon in 2000, with mines in Australia and the United States. Other major zircon producers in order of decreasing production were Richards Bay Minerals (RBM) of Australia, Namakwa Sands (Pty.) Ltd. of South Africa, DuPont of the United States, and Tiwest Joint Venture of Australia.

Australia.—Australia was one of the two largest producers of zircon concentrates in the world (table 5). In 2000, major producers of zircon concentrates, in order of estimated zircon production, were Iluka Resources (formerly RGC Ltd. and Westralian Sands Ltd.), Tiwest, Consolidated Rutile Ltd. (CRL), and Cable Sands Ltd. (CSL). Australian zircon production for 2000 was as follows: Iluka, 194,000 t; Tiwest, 91,000 t; CRL, 46,000 t; CSL, 30,000 t; and New South Wales producers, 4,000 t (Mineral Sands Report, 2001b). Total Australian production in 2000 was reported to be 353,000 t, a decrease from the 1999 level.

Worldwide production from Australian-based Iluka was 315,000 t of zircon in 2000, a decrease from the 331,000 t in 1999 (Iluka Resources Ltd., 2001, p. 9). The company operated eight mines in Australia and two in the United States. Iluka's Australian subsidiary, WA Titanium Minerals, operated six mines in Western Australia, two of which opened in 2000. The company commissioned the Capel North West Mine in January, near Capel, Western Australia. In October, WA Titanium brought online its second operation, the North Mine and Newman concentrator near Eneabba, Western Australia. Other mining operations were the South Mine near Eneabba and the Yoganup, Yoganup extended, and Busselton mines in the southwestern region. Iluka's two east coast mines, in which it has a 43% interest, were operated by CRL on North Stradbroke Island, New South Wales.

Iluka upgraded the ore grade at its Ouyen deposit in northwestern Victoria by 28%. The inferred resource at Ouyen was increased by 1.7 Mt to 7.7 Mt grading 11.4% heavy minerals and containing 40% ilmenite, 15% rutile, and 9% zircon (Iluka Resources Ltd., 2000).

Iluka calculated resources for two of its heavy-mineral sands deposits in the Perth Basin of Western Australia. The Red Gully deposit to the north and the Dandalup deposit to the south of Perth displayed resources of 942,000 t of heavy minerals (Iluka Resources Ltd., 2000).

Australian Zirconia Ltd., a wholly owned subsidiary of Alkane Exploration Ltd., announced it had produced a 99.3% zirconium oxide and hafnium oxide product from its Dubbo hard-rock zirconium-bearing deposit in New South Wales. DEMA Pty. Ltd. was the feasibility study manager and consultant for the project. The multimineral deposit is located on the Toongi alkaline intrusive that contains hafnium, lanthanides, niobium, tantalum, yttrium, and zirconium in the igneous rock trachyte. Based on a planned 200,000 t/yr sulfuric acid leach process, the plant was expected to produce 3,500 t/yr zirconium oxide (and hafnium oxide), 500 to 1,500 t/yr yttrium-lanthanide concentrate, and 900 t/yr tantalum-niobium pentoxide concentrate (Australian Zirconia Ltd., Dubbo zirconia project, accessed May 8, 2001, at URL http://www.alkane.com.au/zirconia.html).

Basin Minerals Ltd. announced the completion of a prefeasibility study of its Douglas heavy-mineral sands deposit discovered in the Murray Basin in western Victoria. The Douglas deposit covers an area of 5,860 square kilometers and has a resource of 22.4 Mt of heavy minerals. The area contains the Acapulco, Bondi, Bondi East, and Echo strandline deposits containing 11.3 Mt of ilmenite (including leucoxene), 1.26 Mt of rutile, and 1.62 Mt of zircon. The project has a projected startup date for 2003 (Basin Minerals, [undated], Mineral sands exploration overview—Douglas project, accessed May 2, 2001, at URL http://www.basinminerals.com.au/projects.html).

Basin Minerals explored five heavy-mineral sands deposits in the Murray Basin area of South Australia, Victoria, and New South Wales. The principal deposits were the Douglas project in Victoria, the Culgoa project in northern Victoria, the Baranald-Swan Hill in New South Wales and Victoria, the Oakville in northern South Australia, and the Pooncarie in western New South Wales. Total resources of the Douglas and Culgoa deposits were 24.4 Mt of heavy mineral concentrates contained in 393 Mt of ore grading 6.2% heavy minerals (Basin Minerals, [undated], Mineral sands exploration overview—Table 1, accessed May 2, 2001, at URL http://www.basinminerals.com.au/projects.html).

Basin Minerals acquired additional land adjacent to its Douglas deposit in Victoria. The State of Victoria awarded successful bids to Basin Minerals for block 2 in the Murray Basin which includes the former CRL WIM 100 deposit with 860 Mt of ore grading 5.9% heavy minerals (Mineral Sands Report, 2000c).

BeMaX Resouces NL announced the results of its pilot plant at its Ginkgo mineral sands joint venture (MSJV). The MSJV partners are BeMaX (50%), Imperial Mining (Aust) NL (25%), and Probo Mining Pty. Ltd. (25%). Located 120 kilometers (km) north of Mildura, Victoria, the Ginkgo deposit has an inferred resource of 260 Mt grading 2.6% heavy minerals. Initial tests showed product suitable for market including ilmenite, rutile, leucoxene, and zircon (BeMaX Resources NL, April 3, 2000, Update—Ginkgo mineral sands deposit, accessed March, 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

BeMaX purchased Imperial Mining's 25% share of the MSJV, raising BeMaX's holdings to 75%. Imperial Mining was a wholly owned subsidiary of Imperial One Ltd. (BeMaX Resources NL, October 10, 2000, Completion of purchase of Imperial Mining (Aust) NL, accessed March 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

BeMaX released information on a heavy mineral strandline discovery that straddles BeMaX's BIP joint-venture property and the property of Iluka Resouces in the Murray Basin. The adjacent Snapper (BeMaX) and Trelega (Iluka) deposits straddle the mining exploration claims at the southwest edge of the BIP joint venture EL5474 property in Victoria (BeMaX Resources NL, October 10, 2000, Mineral Sands discovery straddles boundary of BeMaX's and Iluka's properties, accessed March 13, 2001, via URL http://www.bemax.com.au/Announcements00.html).

Mineral Deposits Ltd. (MDL) stated that it would restart its Viney Creek dredge mine in New South Wales in 2001 because of increased demand for heavy minerals and a weak Australian dollar against the U.S. dollar. The 2,500-ton-per-hour dredge was placed on standby in April 1999 because of weak demand for rutile and zircon. The dredge will be refurbished in the last quarter of 2000. MDL's Hawks Nest dry mill continued to operate with feed from its smaller dredge operation at Fullerton,

Digitized by Google

New South Wales (Mineral Sands Report, 2000e).

Tiwest, an Australian collaboration of U.S.-based Kerr McGee Chemical's LLC subsidiary KMCC Western Australia Pty. Ltd. and Australian-based Ticor Resources Pty. Ltd., produced zircon from its Cooljarloo Mine in Western Australia. In 2000, Tiwest processed 918,000 t of heavy-mineral concentrates to produce 91,000 t of zircon, compared with 548,498 t of heavy-mineral concentrates and 60,188 t of zircon produced in 1999 (Minerals Sands Report, 2001c). The large increase in production was the result of the Cooljarloo Mine upgrade project in 2000. The capacity of heavy-mineral concentrates was increased to 675,000 t/yr from 535,000 t/yr, a 20% gain. Tiwest's expansion cost was 20 million Australian dollars ($A) and was designed and implemented by contractor HBH Consultants (The Institution of Engineers, Australia, 2001, Australian engineering awards 2000—Cooljarloo mine upgrade project for the Tiwest joint venture, accessed March 22, 2001, at URL http://www.ieaust.org.au/events/aeea_entrants/aeea_entrantdetails8.html).

RZM Pty. Ltd. purchased Western Metals Ltd.'s 30% stake in the Wemen heavy-mineral sands project in the Murray Basin, Victoria, for $A5 million. Following the buyout, RZM entered into a 50-50 joint venture with the Australian company Sons of Gwalia for its Murray Basin mineral resource tenements and freehold land and a 50% share of RZM's heavy-mineral sands processing equipment and operations at Tomago, New South Wales. Production from the deposit is scheduled for 2001. Wemen is forecast to produce 10,000 t/yr of zircon over the mine's 6-year life (Industrial Minerals, 2000a).

Brazil.—Millennium Inorgânica Chemicals do Brazil S/A announced it would invest $31 million to upgrade its heavy-mineral sands output at its Mataraca Mine at Guaju, Paraiba State. The installation of a new dredging operation is expected to improve recoveries and lower overall operating costs. The upgrade was expected to be completed by yearend 2001 (Industrial Minerals, 2000f). In 1999, the mine produced about 110,000 t of ilmenite, 2,000 t of rutile, and 16,000 t of zircon (Titanium Minerals Outlook, 2000b). Millennium Inorgânica Chemicals do Brasil S/A produced 61.5% of the zircon concentrate mined in Brazil in 1999. Total Brazilian production of zircon in 1999, the latest available preliminary data, was 29,448 t (Esteves dos Reis, 2001).

Other zircon producers in Brazil are operated by Industrias Nucleares do Brasil S/A (INB), a wholly owned subsidiary of Comissa Nacional de Energia Nuclear. INB produces up to 9,800 t/yr of zircon from its mines in Buena and Delta Paraíba in Rio de Janeiro, Cumuruxatiba in Joacema, and Alcobaça in Bahia.

China.—Production of zircon is estimated to be 20,000 t or less in 1999, which were the latest available data. China was a net importer of zirconium materials in 1999, importing 131,000 t with 73% as zircon concentrates, 18% as bagged zircon or flour, 8% as opacifiers, and 1% other. The principal market for zircon in China is ceramics with an estimated 60% share of the market. Milling capacity is estimated to be 74,000 t/yr and is located mainly in Guangzhou Province, the center of China's ceramic industry. Nanhai is the largest producer of zircon flour with a capacity of 15,000 t/yr out of an estimated 50,000 t/yr capacity. The principal producers of opacifiers are Atofina Chemicals, Inc., and China Glaze Co. Ltd. Total opacifier capacity is estimated to be 24,000 t/yr (Mineral Sands Report, 2000a).

CRL announced the sale of its Chinese-based milling plant, Changzhou Dongao Zirconium Products Ltd., to Johnson Matthey plc in November. The mill has a capacity of 5,000 t/yr. Johnson Matthey plans to upgrade the facility, raise capacity, and install equipment for tile products (Mineral Sands Report, 2000b)

Deqing Biochemistry General Co. (DBGC) announced it was producing zirconium chemicals, including zirconium oxychloride, carbonate, sulfate, acetate, and dioxide, from its plant in Deqing, Zhejiang Province. Capacities for DBGC's zirconium products were 750 t/yr for zirconium oxychloride, 300 t/yr for zirconium carbonate, and 300 t/yr for zirconium sulfate. An expansion in 2001 is expected to increase DBGC's zirconium compound capacity to 15,000 t/yr (Jiang Dongming, Deqing Biochemistry General Corp., written commun., 2001).

India.—Indian Rare Earths Ltd. (IRE) was the eighth largest producer of zircon in the world from its mine at Chavara. IRE produced 22,000 t of zircon in 2000 (Mineral Sands Report, 2001c).

MDL and Iscor Ltd. have signed a memorandum of understanding to form an alliance to develop two heavy-mineral sands deposits in Tamil Nadu State. The Tamil Nadu deposits at Kudiraimozhi and Navaladi-Sattankulam contain 1 billion metric tons of ore grading 6.2% ilmenite, 0.4% rutile, and 0.7% zircon (Mineral Deposits Ltd., November 1, 2000, Announcements—Indian mineral sands project, accessed June 14, 2001, via URL http://www.mineraldeposits.com.au/Announcements2000.html).

Kerala Minerals and Metals Ltd. (KMML) is planning an expansion of its operations at Chavara. KMML has reserves of 18 Mt grading up to 50% heavy minerals. The heavy minerals contain 65% to 75% ilmenite, 5% to 7% rutile, and 4% to 8% zircon (Titanium Minerals Outlook, 2000a).

Kenya.—Tiomin Resources Inc. of Toronto, Canada, raised Can$5 million through the private offering of warrants for investments in its Kwale heavy-mineral sands deposit. The cash was expected to be used to acquire surface mining rights at its Kwale deposit and to finalize detailed engineering plans for the heavy-mineral sands mine (Mineral Sands Report, 2000g). The Kwale deposit is divided into three economic zones of Pliocene age: the north, the central, and the south dunes. Zircon and other heavy minerals are contained in the Magarini Formation sands, which form a belt of low hills believed to be aeolian in origin. Resources of the Kwale deposit are 200 Mt of ore containing 0.6 Mt of zircon (Tiomin Resources Inc., [undated], Kwale—Rutilite, ilmenite, and zircon, accessed May 16, 2001, via URL http://www.tiomin.com/s/Properties.asp?PropertyInfoID=316&PropertyMapID=1034).

Based on the results of a feasibility study by LTA Process Engineering Pty. Ltd. of South Africa and Ausenco of Australia, Tiomin planned to start construction at Kwale in 2001. During its first 6 years, the mine is expected to produce 37,000 t/yr of zircon. Kwale has a mine life of 14 years (Industrial Minerals, 2000e).

Mozambique.—Kenmare Resources plc of Dublin, Ireland, bought the heavy-mineral sands dry separation plant from BHP Ltd's Beenup Mine in Western Australia, which closed in 1999 after being in operation less than a year (Industrial Minerals, 2000d). The 650,000 t/yr plant was purchased for $4.7 million and is expected to be installed at the Moma titanium minerals project in Mozambique (Kenmare Resources plc, 2000a).

Kenmare had previously purchased BHP's wet concentrator in January for $1.4 million (Industrial Minerals, 2000c). The aquisition of both plants from the Beenup minesands project is

Digitized by Google

expected to save Kenmare in excess of $60 million in capital expenditures. The Moma titanium project is scheduled to begin production in late 2002 (Kenmare Resources plc, 2000b)

South Africa.—Iscor Ltd. announced it would begin development of its Hillendale Mine in Kwazulu Natal Province in the second quarter of 2001. The initial production capacity of the mine will be 50,000 t/yr of zircon but will increase to 100,000 t/yr by 2003. Other heavy mineral capacities, at full production, are 550,000 t/yr for ilmenite, 40,000 t/yr for rutile, and 10,000 t/yr for leucoxene. Reserves at the Hillendale deposit are 73 Mt grading 5.6% valuable heavy minerals, excluding magnetite (Iscor Ltd., [undated], Heavy minerals—Hillendale, accessed April 22, 2001, via URL http://www.iscor.com/mainframe.asp?imgname=01). Construction of the Hillendale mine and wet concentrator plant began in April at a cost of $137 million. Construction also began on a central mineral separation plant at Empangeni, 20 km from the mine site. The separation plant was expected to come onstream in the third quarter (Industrial Minerals, 2000b).

Ticor Ltd. announced in October that it has begun a review of Iscor's heavy-mineral sands deposits in South Africa. Ticor is interested in acquiring a 50% share of the project, which has reserves of 16 Mt of heavy minerals. The project consists of three deposits: the Hillendale, the Fairbreeze, and the Gravelotte. The Hillendale is scheduled to be the first mine developed. The combined mine life of the three deposits is at least 20 years (Mineral Sands Report, 2000f).

Foskor Ltd. commissioned a third zircon smelting furnace for the production of zirconia with a capacity of 1,500 t/yr. Total zirconia capacity of the three operations is 5,000 t/yr. In addition to producing synthetic zirconia from zircon, Foskor produced an estimated 2,000 to 3,000 t of baddeleyite (natural zirconia) from its Palabora Mine at Phalaborwa in 1998, which were the latest available data. The company ceased production of baddeleyite in June 1999 as a result of declining ore grades (Industrial Minerals, 2000g).

Namakwa Sands, a wholly owned subsidiary of Anglo American plc, increased its heavy-mineral sands production as a result of the completion of its phase two expansion. Construction of the project, which was funded at 1.2 billion rand (R) in 1997, was completed in 1999. Zircon was produced from its mine at Brand-se-Baai. Zircon concentrate produced from its dry mill at Koekenaap increased to 106,800 t in 2000 from 91,900 t in 1999 (Mineral Sands Report, 2001a). The phase two expansion increased ore capacity to 12 million metric tons per year (Mt/yr) from 4 Mt/yr. Zircon capacity increased to 133,000 t/yr with a mine life of 35 years.

Amagamet Canada, a division of Premetalco Inc., was the North American sales agent for Namakwa Sands of South Africa. Amagamet reported the purity of the Namakwa South Africa zircon to be 66% minimum, ($ZrO_2 + HfO_2$), 0.06% maximum (Fe_2O_3), and 0.12% maximum (TiO_2) (Amagamet Canada, [undated], Zircon, accessed June 14, 2001, at URL http://www.amalgamet.com/busmizi.htm).

Palabora Mining Co. Ltd. continued to produce baddeleyite from its open pit mine. Open pit mining at the Palabora Mine is scheduled to cease in 2002, and the company will begin recovering ore by underground mining methods. In 1999, the latest available data, Palabora produced 7,486 t of baddeleyite, an 8% decrease from 1998. The decreased production was attributed to a decline in ore grade with increasing depth of the pit. Palabora also produced zirconium sulfate tetrahydrate and milled baddeleyite (Palabora Mining Co. Ltd., 2000, p. 9).

RBM completed construction of a new heavy-mineral sands processing plant. Completed in October 1999, the plant is designated mining plant E (Joseph, 2001).

Outlook

The global demand for zirconium materials was largely in balance in 2000. Growth was expected to increase by 3% per year over the next few years, and new deposits are expected to come online. Prices were forecast to rise in the near term in response to higher energy costs. During the next few years, however, the supply and demand of zircon is expected to be in closer balance as new deposits and plant expansions come online, especially in the United States and Australia. Expansions in supply are expected in Mozambique and South Africa, and further exploration and development efforts are underway in Australia, Canada, India, Kenya, South Africa, Ukraine, and the United States. Production of zircon in the United States was expected to increase during the first decade of the 21st century.

Consumption, apparent	W	W	W	W	W
Stocks, December 31, producer 4/	822	982	985	W	818 e/

e/ Estimated. W Withheld to avoid disclosing company proprietary data.
1/ Data are rounded to no more than three significant digits.
2/ Includes insignificant amounts of baddeleyite.
3/ Excludes foundries.
4/ Excludes intermediate oxides associated with metal production.
5/ Includes germanium oxides and zirconium dioxides.

TABLE 2
PUBLISHED YEAREND PRICES OF ZIRCONIUM AND HAFNIUM MATERIALS

Specification of material	1999	2000
Zircon:		
Domestic, standard-grade, bulk, per short ton 1/	$300.00 r/	$340.00
Domestic, 75% minimum quantity zircon and aluminum silicates, bulk, per short ton 1/	267.00	267.00
Domestic, premium-grade zircon, bulk, per short ton 1/	490.00	497.00
Imported sand, ceramic application, f.o.b., bulk, per metric ton 2/	320.00-360.00	345.00-375.00
Imported sand, refractory application, f.o.b., bulk, per metric ton 2/	320.00-360.00	340.00-370.00
Imported sand, foundry sand application, f.o.b., bulk, per metric ton 2/	320.00-360.00	340.00-370.00
Zirconium: 5/		
Powder, per pound	75.00-150.00	75.00-150.00
Sponge, per pound	9.00-12.00	9.00-12.00
Sheets, strip, bars, per pound	20.00-50.00	20.00-50.00
Hafnium, sponge, per pound 5/	75.00-95.00	75.00-95.00

See footnotes at end of table.
